ABSTRACT:

The pharmacokinetics, metabolism, and brain penetration of the neurokinin 1 (NK₁) receptor antagonist (substance P receptor antagonist), aprepitant (MK-0869), were examined in ferrets. This species exhibits human-type NK₁ receptor pharmacology and is of proven value in the identification of clinically useful drugs for the treatment of chemotherapy-induced nausea and vomiting in humans. After a single p.o. dose of aprepitant at 1 or 2 mg/kg, plasma levels of the compound were between 200 and 270 ng/ml, 24 h after dosing. In the brain cortex, concentrations of aprepitant reached between 80 and 150 ng of tissue 24 h after dosing. The predominant radioactive component present in the plasma and the brain of ferrets at 24 or 48 h after a single oral dose of [¹⁴C]aprepitant at 3 mg/kg was the parent compound itself. The slow plasma clearance of aprepitant (~1.5 ml/min/kg) and its abundance in ferret brain were in accord with its efficacy in blocking the retching and vomiting at 24 and 48 h postdose when ferrets were challenged with the emetic anticancer drug, cisplatin. When aprepitant and some of its metabolites were assessed for their in vitro binding affinity to the human NK₁ receptor, aprepitant demonstrated the highest affinity. Collectively, these data suggested that aprepitant, rather than its metabolites, was responsible, primarily, for the antiemetic activity of this compound in the male ferret.

One of the unpleasant side effects associated with chemotherapy is the intense feeling of nausea often accompanied by vomiting. Among the agents used to alleviate these conditions are H₁-blockers (Bergman and Spealman, 1988; Tomato et al., 1994), D₂-blockers (Jovanovic-Micic et al., 1995; Mystakidou et al., 1998), 5-hydroxytryptamine₃ blockers (Gregory and Ettinger, 1998; Ye et al., 2001), and cannabinoids (Abrahamov et al., 1995; Mechoulam and Hanu, 2001). More recently, efforts have been made to determine the efficacy of NK₁ receptor antagonists against chemotherapy-induced nausea and vomiting (Bountra et al., 1993; Tattersall et al., 1994; Beattie et al., 1995; Gardner et al., 1995, 1996; Harrison et al., 2001). Using the ferret, it has been established that brain penetration of NK₁ antagonists is essential to prevent drug-induced (cisplatin) emesis, and several compounds have been shown to be efficacious in this regard (Watson et al., 1995; Gonsalves et al., 1996; Rudd et al., 1996; Tattersall et al., 1996; Rupniak et al., 1997; Singh et al., 1997; Zaman et al., 2000; Harrison et al., 2001). One of these compounds is aprepitant (MK-0869; 5-[(2R,3S)-2-[(1R)-1-[3,5-bis(trifluoromethyl)phenyl][ethoxy]-3-(4-fluorophenyl)-4-morpholinyl]methyl]-1,2-dihydro-3H-1,2,4-triazol-3-one) (Hale et al., 2000; Tattersall et al., 2000; Harrison et al., 2001).

Aprepitant exhibited a protracted effect in blocking the cisplatin-induced emesis in ferrets (Tattersall et al., 2000; Harrison et al., 2001). This is a crucial effect because, in humans undergoing treatment with chemotherapeutic agents such as cisplatin, the nausea and vomiting may persist for many days after the initial cancer treatment (Navari et al., 1999; Campos et al., 2001; Coccuy et al., 2001). Brain penetration and subsequent receptor occupancy are important factors in mediating the beneficial effects of aprepitant in the vomiting induced in the ferret by cisplatin. However, it is not known whether the extended antiemetic activity resides with aprepitant or with its metabolites or, indeed, with both parent compound and metabolites.

For this reason, the pharmacokinetics of aprepitant and the metabolism of radiolabeled aprepitant were examined in ferrets after a single oral dose of the compound. In addition, the brain levels, as well as the identification of metabolites in the ferret brain, were evaluated. Previously, several metabolites of aprepitant were identified in pri-
mary rat hepatocyte cultures (S. E. Huskey, R. I. Sanchez, G. A. Doss, B. H. Arison, B. J. Dean, J. Pang, K. Leung, B. Zhu, M. P. Braun, P. E. Finke, D. Luffer-Atlas, T. A. Baillie, and S. H. L. Chiu, manuscript submitted for publication), and this information was used to facilitate the identification of the in vivo metabolites in ferret, as described herein. Furthermore, to gain insight into the pharmacologically active entities in the ferret brain, the NK1 receptor binding affinities of aprepitant and authentic metabolites were evaluated. These experiments led to the conclusion that the major entity responsible for the beneficial, antiemetic effects of aprepitant in the ferret was the parent molecule itself.

**Materials and Methods**

**Chemicals.** Aprepitant (Fig. 1) was prepared by Merck Process Research (Rahway, NJ). [Morpholine-2-14C]aprepitant (specific activity 29.83 μCi/mg) was synthesized by the Merck Labeled Compound Synthesis Group (Rahway, NJ). The desfluoro derivative of aprepitant and several metabolites, including M-1, M-3, M-4, M-5, and M-6 (Fig. 1) were synthesized by Merck Medicinal Chemistry (Rahway, NJ). Metabolite M-2 was synthesized by Merck Medicinal Chemistry (Terlings Park, UK).

**Dose Preparation.** For pharmacokinetic studies, the i.v. dose of aprepitant (0.5 mg/kg) was administered in a vehicle consisting of ethanol/propylene glycol/water (1:6:3 by volume, 0.5 ml/kg) and the oral dose (1 mg/kg) in a suspension in 0.5% aqueous methylcellulose containing 0.02% sodium lauryl sulfate (1 ml/kg). For the brain penetration studies, oral doses of aprepitant (1 and 2 mg/kg) were prepared in ethanol/propylene glycol/water (1:6:3 by volume, 1 ml/kg), and one oral dose of [14C]aprepitant (3 mg/kg; specific activity 18 μCi/mg) was formulated in a suspension in 0.5% aqueous methylcellulose containing 0.02% sodium lauryl sulfate (1 ml/kg). The i.v. solutions were passed through a sterile 0.45-μm filter before dosing.

**Pharmacokinetic Studies.** Male ferrets (~1–2 kg) were purchased from Marshall Farms USA Inc. (North Rose, NY) or a registered breeder of ferrets in the UK. The animals were housed under standard conditions, with a 12-h light/dark cycle, in the Comparative Medicine facilities of Merck Research Laboratories, Rahway, NJ, or Merck, Sharp and Dohme Laboratories, Terlings Park, UK. Animals were allowed access to commercial chow and water ad libitum. They were not fasted overnight, but food was withdrawn before dosing and then returned 4 or 6 h after dosing. Animals were allowed unrestricted access to water during the study period.

For the pharmacokinetic studies, three male ferrets were used in a crossover design. They were dosed with aprepitant at 0.5 mg/kg by bolus injection via a percutaneously placed cephalic vein catheter. After a 2-week washout period, the same three ferrets were dosed orally by gavage at 1 mg/kg. Blood samples (1 ml) were obtained by venipuncture from the jugular vein into heparinized Vacutainer blood collection tubes at predose, 5 (i.v. only), 15, or 30 min, and 1, 2, 4, 6, 8, 10, 24, 32, 48, 56, and 72 h after dosing. Plasma was prepared by centrifugation of the blood and stored at −20°C until analysis.

**Brain Penetration Studies.** Adult male ferrets (n = 3–4 per time point), weighing ~1.0–2.0 kg, were dosed with aprepitant orally, by gavage, at a dose of 1 or 2 mg/kg. Terminal blood samples were collected from the abdominal aorta of anesthetized ferrets into heparinized Vacutainer blood collection tubes at 1, 2, 4, 6, 8, 10, 24, 32, 48, 56, and 72 h after dosing. Plasma was prepared by centrifugation at 3000 g for 10 min. Ferret brain cortices were collected and stored at −70°C until analysis.

Another group of male ferrets (n = 2 per time point), weighing ~2 kg, received a single oral dose of [14C]aprepitant, by gavage, at a dose of 3 mg/kg. Terminal blood samples were collected by cardiocentesis from anesthetized ferrets at 24 or 48 h post dose. Plasma was prepared by centrifugation at 3000 g for 10 min. Entire ferret brains were collected and stored at −70°C until analysis.

**Preparation of Plasma Samples for LC-MS/MS Analysis.** Plasma samples (0.2 ml), from ferrets in the pharmacokinetic study, were mixed with 20

Following percolation through the cartridge, the solid phase was washed with 6 ml of water and eluted with 3 ml of methanol. The methanol eluent was evaporated to dryness under a stream of nitrogen, resolubilized in 300 μl of mobile phase (see below), and analyzed by LC-MS/MS.

Alternatively, aliquots of the plasma samples (50 μl) from ferrets, in the brain penetration study, were transferred to a 96-well plate, mixed with 5 ng of internal standard, and precipitated with 100 μl of acetonitrile. After vortex-mixing, samples were spun in a centrifuge at 3000 g for 10 min. Aliquots (5 μl) of the supernatants were subjected to LC-MS/MS analysis.

Preparation of Plasma Samples for HPLC Analysis. Plasma proteins were precipitated by the addition of 2 volumes of acetonitrile to 3 ml plasma samples obtained from animals in the brain penetration study using [14 C]-aprepitant. After centrifugation at 3000 g for 10 min. The supernatants were transferred to clean glass tubes and evaporated to dryness under N2. The residues were resuspended in 1 ml of 40% aqueous methanol and 250 to 400 μl aliquots of these solutions were analyzed by HPLC (see below).

Extraction of Brain Homogenates for LC-MS/MS Analysis. Half of the brain cortex obtained from ferrets in the brain penetration studies were weighed and homogenized with 1 ml of deionized water. To each homogenate was added 100 ng of internal standard in methanol, and the suspension was subjected to sonication for 5 min. Aliquots (50 μl) were transferred to a 96-well plate and 100 μl of acetonitrile was added. The samples were vortex-mixed and spun in a centrifuge at 3000g for 10 min. Aliquots (25 μl) of the resulting supernatants were subjected to LC-MS/MS analysis (see below).

Extraction of Brain Homogenates for HPLC Analysis. Entire brains from ferrets were weighed and homogenized with 3 volumes of deionized water. The proteinaceous material in each homogenate (10 ml) was precipitated by the addition of 9 volumes (v/v) of acetonitrile. These suspensions were thoroughly vortex-mixed, sonicated for 5 min, and spun in a centrifuge at 3000g for 10 min. The supernatants were transferred to clean glass tubes, and the pellets were re-extracted with methanol (10 ml). The methanolic extracts were combined with the acetonitrile supernatants prior to loading onto Varian Bond Elut C18 cartridges adapted with Acrodex glass filters (Gelman Instrument Co., Ann Arbor, MI). After sample application, the cartridges were washed with 5 ml of a 2:1:1 mixture, by volume, of methanol/acetonitrile/distilled water. The eluents collected after sample loading and during the cartridge wash were combined and evaporated to dryness under N2. The residues were redissolved in 5 ml of methanol, vortex-mixed, subjected to sonication, and spun in a centrifuge as described previously; and the supernatants were transferred to clean glass tubes and evaporated to dryness under a stream of N2. The residues were redissolved in 1 ml of 40% aqueous methanol, and aliquots (400 μl) were analyzed by HPLC (see below).

Radioactivity Measurements. For an estimate of total radioactivity, duplicate aliquots of plasma (0.1–0.5 ml) were counted directly by liquid scintillation counting following the addition of scintillation cocktail (Ultima-FLO M; PerkinElmer Life Sciences, Boston, MA). Triplicate aliquots of brain homogenates (0.4–0.7 g), prepared as described previously, were transferred by pipette into paper combustion cones and air-dried overnight prior to combustion. These samples were combusted in an oxidizer (model 307; PerkinElmer Life Sciences) and their radioactive content was estimated by liquid scintillation counting (Beckman Coulter, Inc., Fullerton, CA).

HPLC Analysis with Radiometric Detection. A Shimadzu HPLC system (Shimadzu Scientific Instruments Inc., Columbia, MD), consisting of two pumps (LC-10AD), a controller (SCL-10A), an autosampler (SIL-10A), a radiomonitor (INUS Systems Inc., Tampa, FL), and a fraction collector (model FC 204; Gilson Medical Electronics, Middletown, WI), was used for all analyses.

Chromatography was performed on a Zorbax RX-C8 (4.6 × 250 mm; MAC-MOD Analytical Inc., Chadds Ford, PA) column for both plasma and brain extracts. Method A. The mobile phase consisted of solvent A (10 mM ammonium acetate in water) and solvent B (7.2 mM ammonium acetate in 7.2% methanol and 92.8% acetonitrile, v/v). Method B. Elution solvents C (10 mM ammonium acetate in water containing 0.1% trifluoroacetic acid) and D (7.2 mM ammonium acetate in 7.2% methanol, 92.7% acetonitrile, and 0.1% trifluoroacetic acid, by volume) were used in this method. The eluent flow rate was 1 ml/min using a linear gradient from 35 to 80% B or 35 to 80% D in 40 min for methods A and B. Radioactivity profiles were obtained by on-line profiling using a radiomonitor (INUS Systems Inc.) connected to the column.

LC-MS/MS Analysis of Plasma and Brain Samples. Quantification of aprepitant in plasma and brain was performed on a tandem mass spectrometer (Sciex API III-ESI). Applied Biosystems, Foster City, CA) using a heated nebulizer interface. Chromatographic separation was achieved on a Spherisorb C8 column (4.6 × 50 mm; 5 μm; Waters, Milford, MA) using a mobile phase consisting of 55% acetonitrile, 45% 10 mM ammonium acetate, and 0.1% formic acid, by volume. The flow rate was 1 ml/min. In this system, aprepitant and the internal standard coeluted at approximately 1.5 min. The dwell time for the multiple reaction monitoring was 450 ms. A peak was defined typically by 10 to 12 data points. The positive ion mode was used. Multiple reaction monitoring using the precursor → product ion combinations of m/z 535→179 and 517→161 was used for quantification of aprepitant and the internal standard, respectively. The levels of aprepitant in plasma or brain extract were determined by using standard curves in which control plasma (50 or 200 μl) or control brain cortex extract (50 μl) was spiked with increasing concentrations of aprepitant (0.25–1000 ng) and 20 or 100 ng of internal standard. A power regression fit, [Y = kX^a], was used to quantify the unknowns. Standards and samples were extracted concurrently. The limits of quantification for aprepitant were 5 ng/ml in plasma and 5 ng/g of tissue in brain, respectively.

Determination of Pharmacokinetic Parameters. The areas under the plasma concentration versus time curves (AUCs) were calculated using the linear trapezoidal method for the ascending portion of the curve and the logarithmic method for the descending portion of the curve. The area under the maximum concentration to infinity was calculated by dividing the last measurable plasma concentration by the elimination rate constant, which was estimated from the plasma concentration versus time curve by linear regression at the terminal phase of the semilogarithmic plot. The plasma clearance of aprepitant was calculated from the dose divided by the total AUC. The apparent volume of distribution at steady state was determined as Dose × [AUMC(AUC)]^2, where AUMC is the area under the first moment of the drug concentration versus time curve from time 0 to infinity. The t1/2 was calculated by dividing 0.693 (ln 2) by the elimination rate constant. For the oral dose, the Cmax and Tmax values represented the maximal concentration observed in plasma and the time required to reach Cmax values, respectively. Oral bioavailability (% F) was calculated from the mean AUC values, corrected for dose, from the oral and i.v. doses.

In Vivo Binding Affinity of Aprepitant and Metabolites to Human NK1 Receptor. The human NK1 receptor was cloned and stably expressed in Chinese hamster ovary cells at a level of 1 × 10^7 receptors per cell (Cascieri et al., 1992; Fong et al., 1992). Briefly, cells were grown in monolayer culture, detached from the plate using Enzyme-free Cell Dissociation Solution (Specialty Media, A Division of Cell & Molecular Technologies Inc., Phillipsburg, NJ) and washed prior to the assay. [125I-Tyr 8 -substance P (0.1 nM, 2200 Ci/mmol; PerkinElmer Life Sciences) and the compound under investigation (in 5 μl of dimethyl sulfoxide) were incubated with 5 × 10^4 Chinese hamster

Concentrations of aprepitant in ferret plasma and brain. After p.o. administration to ferrets at 1 or 2 mg/kg, levels of aprepitant were high in the plasma and brain (Table 2, Fig. 2). The observed plasma $C_{\text{max}}$ values were 353 and 995 ng/ml, and $T_{\text{max}}$ occurred at 10 h post dose for both the 1 and 2 mg/kg doses. Similarly, the brain $C_{\text{max}}$ values were 160 and 384 ng/ml at 10 h post dose. Of note, at 24 h post dose, high levels of aprepitant were still present in the plasma (1 mg/kg, 213 ± 37 ng/ml; 2 mg/kg, 266 ± 24 ng/ml) and also in the brain (1 mg/kg, 84 ± 10 ng/g of tissue; 2 mg/kg, 145 ± 17 ng/g of tissue). The brain-to-plasma ratios of aprepitant, ranging from 0.12 to 0.55 at selected time points at either dose level, increased with time and reached their highest ratios at 10 or 24 h postdose. Collectively, the data suggested that aprepitant was abundant in brain, especially at 10 and 24 h post dose.

Brain Penetration of [14C]Aprepitant in the Ferret. Total radioactivity in ferret plasma and brain. The concentrations of total radioactivity in plasma and brain of ferrets, following an oral dose of [14C]aprepitant at 3 mg/kg, are shown in Table 3. The levels of radioactivity were ~600 and ~450 ng Eq/ml in plasma 24 and 48 h post dose, whereas levels in the brain were quite similar at ~450 and ~350 ng Eq/g of tissue, respectively. The mean brain-to-plasma ratio of total radioactivity was ~0.8, ranging from 0.67 to 0.94 at 24 or 48 h post dose.

Metabolite profiles and concentrations of [14C]aprepitant in ferret plasma and brain. The radioactive metabolite profile of plasma, at 48 h postdose, is shown in Fig. 3, panel A. [14C]Aprepitant was the major component, accounting for 70–80% of plasma radioactivity at the 48-h time point after dosing. As described previously (S. E. Huskey, R. I. Sanchez, G. A. Doss, B. H. Arison, B. J. Dean, J. Pang, K. Leung, B. Zhu, M. P. Braun, P. E. Finke, D. Luffer-Atlas, T. A. Baillie, and S. H. L. Chiu, manuscript submitted for publication), aprepitant and its hydroxy-lactam metabolite M-4, coeluted at 27 min using HPLC Method A. However, in this instance, it was confirmed, using HPLC Method B, that [14C]aprepitant, and not M-4, was the major component, accounting for 70–80% of plasma radioactivity.

Concentrations of aprepitant were estimated to be ~360 ng Eq/ml (Table 3). This profile was qualitatively identical with...
that obtained 24 h postdose (data not shown), and the concentrations of aprepitant were estimated to be ~530 ng Eq/ml at the 24-h time point (Table 3). Several metabolites, M-1, M-3, and M-6 (Fig. 1), were detectable at low concentrations at the 48-h time point (Fig. 3). 

Brain extracts, obtained from the same ferrets used for the 24- and 48-h plasma studies, were analyzed by HPLC. As shown in Fig. 3, panel B, the radioactivity profile of the extracts revealed a major component that eluted with the same retention time as aprepitant (27

*Estimated from chromatographic profile, as described under Materials and Methods. Two ferrets were used at each time point.

**Fig. 3.** Representative radioactivity profiles of aprepitant from plasma (A) and brain (B) of ferrets following p.o. dosing with [14C]aprepitant at 3 mg/kg.

At 48 h postdose, plasma samples and brain extract from ferrets were subjected to HPLC analysis. Chromatography was carried out on a Zorbax RX-C8 column, as described under Materials and Methods.
min). Based on the radiochromatograms, $^{14}$C-aprepitant accounted for $>60\%$ of the radioactivity recovered from brain at 24 and 48 h, and the concentrations of aprepitant were estimated to be $\sim 350$ and $\sim 230$ ng Eq/g tissue (Table 3). The brain-to-plasma ratios of total radioactivity or aprepitant were estimated to be $\sim 0.64$ (Table 3). In addition, two minor radioactive components, M-1 and M-3, were identified by their coelution with authentic materials by HPLC (Fig. 3).

### Biological Activity of Metabolites of Aprepitant

The potential of metabolites of aprepitant (M-1, M-2, M-3, M-4, M-5, and M-6; Fig. 1) to serve as NK$_1$ receptor antagonists was evaluated using the human NK$_1$ receptor binding assay. When compared with aprepitant (mean $IC_{50} = 0.12 \text{nM}$), all of the metabolites showed much reduced binding affinities, ranging from $\sim 4\times$-fold for M-1 to $\sim 14\times$, $\sim 250\times$, and $\sim 7000\times$ for M-3, M-4, and M-5, respectively (Table 4).

### Discussion

There is strong evidence to suggest that the beneficial effects of substance P antagonists (NK$_1$ receptor antagonists) on nausea and vomiting observed after chemotherapy treatment are dependent on their penetration and subsequent binding in the brain (Watson et al., 1995; Gonsalves et al., 1996; Tattersall et al., 1996; Rupniak et al., 1997; Zaman et al., 2000). Cisplatin administration causes vomiting in ferrets, and this observation has led to the testing of antiemetics in this animal model (Bountra et al., 1993; Tattersall et al., 1994; Beattie et al., 1995; Gardner et al., 1995, 1996; Harrison et al., 2001). In a 4-h observation period, aprepitant (0.3, 1, or 3 mg/kg i.v. or 3 mg/kg p.o.) inhibited completely the emetic response to cisplatin (10 mg/kg i.v.) in ferrets. Furthermore, in a model of acute and delayed emesis, aprepitant (1 or 2 mg/kg once daily) completely prevented retching and vomiting for 72 h in all ferrets challenged with cisplatin (5 mg/kg i.p.) (Tattersall et al., 2000).

The question therefore arose whether metabolites of aprepitant contributed to its excellent duration of action in the ferret. Since the pharmacological effect is correlated with brain penetration, both the plasma and the brain tissue of ferrets were analyzed initially for aprepitant following a single oral dose at 1 or 2 mg/kg. As expected, the levels of aprepitant were high in both plasma and brain at 24 h postdose. Subsequently, radiolabeled aprepitant was administered to ferrets in an attempt to verify whether aprepitant is the major component present in both plasma and the target organ, the brain. Forty-eight hours after a single oral dose of $^{14}$C-aprepitant, the major radioactive component in the plasma was parent drug. Three other minor metabolites (M-1, M-3, and M-6) were also detected. In the ferret brain at this same time point, $^{14}$C-aprepitant was the predominant radioactive component; metabolites M-1 and M-3 were detected at lower levels, and the ratios of aprepitant to M-1 and aprepitant to M-3 were $\sim 4$ and $\sim 4$ at 48 h postdose. The mean brain-to-plasma ratio of aprepitant was estimated to be $\sim 0.64$ in ferrets 24 and 48 h postdose (Table 3), suggesting that aprepitant penetrated the brain readily and was retained there for at least 48 h. Furthermore, the binding of aprepitant and its metabolites to the human NK$_1$ receptor demonstrated that aprepitant was more avidly bound than the metabolites M-1 through M-6. In our experience with numerous NK$_1$ antagonists from several structural classes, the compound binding affinities for the ferret NK$_1$ receptor consistently approximate those of the human NK$_1$ receptor. Collectively, these findings indicate that aprepitant is primarily responsible for preventing cisplatin-induced acute and delayed retching and vomiting in the ferret described by Tattersall et al. (2000).

In humans, aprepitant has proven to be efficacious against chemotherapy-induced nausea and vomiting (Navari et al., 1999; Campos et al., 2001) and is a low-clearance compound (Dr. A. Majumdar, Department of Drug Metabolism, Merck Research Laboratories, West Point, PA, personal communication). The in vitro binding affinities of the metabolites (M-1 through M-6) to the human NK$_1$ receptor showed them to have a much reduced binding affinity ($\sim 4$ to $\sim 7000\times$) when compared with aprepitant (Table 4). Therefore, although the metabolite profiles in human brain are not available, it is likely that aprepitant is responsible for the antiemetic activity observed in humans.

### Acknowledgments

We thank Dr. J. Hale for supplying the destfluoro derivative of aprepitant for the internal standard in pharmacokinetic analysis and metabolite M-1; Dr. P. Finke for supplying metabolites M-3, M-4, M-5, and M-6; and Dr. B. Williams for the synthesis of M-2; Dr. D. Cai for the synthesis of aprepitant. We acknowledge M. Kurtz for the determination of binding affinities of aprepitant and its metabolites to the human NK$_1$ receptor. We thank J. R. Strauss, P. K. Cunningham, and Dr. W. P. Feeney for their skillful technical assistance in the animal studies. We thank Steve Matheson, Desmond O’Connor, and Denise Morrison for skillful analytical assistance. We gratefully acknowledge the support and constructive discussions with Drs. Ron Franklin, David Evans, and Anup Majumdar during the preparation of the manuscript.
