ABSTRACT:
The role of breast cancer resistance protein (BCRP/ABCG2) in limiting the brain and testis penetration of xenobiotic compounds in the blood-brain and -testis barriers was investigated using Bcrp\(^{-/-}\) mice. Tissue/plasma concentration ratios in the brain (\(K_{p,brain}\)) and testis (\(K_{p,testis}\)) obtained under steady-state conditions were significantly increased in Bcrp\(^{-/-}\) mice for PhIP (2-amino-1-methyl-6-phenylimidazo[4,5-b]pyridine), N-hydroxyl PhIP, MelQx (2-amino-3,8-dimethylimidazo[4,5-f]quinoxaline), dantrolene, and prazosin. In addition, the \(K_{p,brain}\) of triamterene and the \(K_{p,testis}\) of 4'-hydroxyl PhIP were also significantly increased in Bcrp\(^{-/-}\) mice. The effect of functional impairment of Bcrp on the brain uptake of PhIP, dantrolene, and daidzein in Bcrp\(^{-/-}\) mice determined using in situ brain perfusion was weaker than that observed on the \(K_{p}\) values. In vitro transcellular transport experiments using cell lines expressing mouse Bcrp or P-glycoprotein (Mdr1a/Abcb1a) showed that, among the tested Bcrp substrates, PhIP, MelQx, prazosin, and triamterene are common substrates of Bcrp and P-glycoprotein. The \(K_{p}\) values of common substrates exhibited a smaller increase both in the brain and testis of Bcrp\(^{-/-}\) mice than expected from the in vitro Bcrp activities. The Bcrp-specific substrates were weak acids, whereas basic or neutral Bcrp substrates were also P-glycoprotein substrates. These results suggest that BCRP limits the tissue penetration of xenobiotic compounds in the blood-brain and -testis barriers, but its in vivo importance is also modulated by P-glycoprotein activity.

The brain and testis are highly protected from the invasion of xenobiotic compounds by the blood-brain barrier (BBB) and blood-testis barrier (BTB). The BBB is formed by brain microvascular endothelial cells, whereas myoid and Sertoli cells are involved in the BTB in addition to the endothelial cells (Bart et al., 2002; Kusuhara and Sugiyama, 2005; Scherrmann, 2005). In addition to the highly developed tight junctions between adjacent cells, the BBB and BTB express multiple xenobiotic transporters characterized by broad substrate specificities. They actively extrude xenobiotic compounds into the circulating blood and, thereby, limit tissue penetration from the circulating blood. On the luminal side of the BBB, ABC transporters, such as P-glycoprotein (P-gp/MDR1/ABCB1), multidrug resistance-associated protein 1 (MRP1/ABCC1) and -4 (MRP4/ABCC4), and breast cancer resistance protein (BCRP/ABCG2), are expressed.

This study was supported by Grants-in-Aid for Scientific Research (A) from Japan Society for the Promotion of Science (JSPS) (KAKENHI 17209005 for Y.S.) and for Scientific Research (B) (KAKENHI 18390046 for H.K.) from Japan Society for the Promotion of Science.

brain penetration of imatinib rather than Bcrp (Bihorel et al., 2007). Recently, we reported for the first time that BCRP limits the penetration of phytoestrogens, such as daidzein, genistein, and coumestrol, into the brain and testis (Enokizono et al., 2007b). On the other hand, there was no difference in the brain distribution of other BCRP substrates, such as dehydroepiandrosterone sulfate (DHEAS), mitoxantrone, pitavastatin, and fluoroquinolones, between wild-type and Bcrp−/− mice (Hirano et al., 2005; Lee et al., 2005; Ando et al., 2007). These results emphasize the difficulties in predicting in vivo relevance from in vitro transport assays.

The purpose of the present study is to determine the quantitative relationship between the transport activities of the compounds by mouse Bcrp and the increase in their tissue/plasma concentration ratios. Adachi et al. (2001) and Yamazaki et al. (2001) previously demonstrated that the corrected flux ratio (CFR), obtained by the ratio of the basal-to-apical and apical-to-basal transport across the monolayers of epithelial cells expressing P-gp divided by the corresponding ratio in mock cells, is a good predictor of in vivo P-gp activity at the BBB (Adachi et al., 2001; Yamazaki et al., 2001). In addition to phytoestrogens (Enokizono et al., 2007b), we investigated the effect of BCRP on the brain and tubular distribution of five compounds, including dietary carcinogens MelIQx and PhIP and drugs (dantrolene, prazosin, and triamterene), using Bcrp−/− mice. Transcellular transport of the compounds across the monolayers of MDCK cells expressing mouse Bcrp was also determined. The CFR for Bcrp was not a good predictor of the increase in Kp values in the brain and testis in Bcrp−/− mice. It was also found that some Bcrp substrates, particularly those exhibiting a marginal increase in Kp values, are also P-gp substrates. The present study proposes that Bcrp plays a significant role in limiting the tissue penetration of xenobiotic compounds, but the impact of functional impairment of Bcrp is also modulated by P-glycoprotein activity on their shared substrates.

Materials and Methods

Materials and Animals. MelIQx and PhIP were purchased from Wako Pure Chemicals (Osaka, Japan), and dantrolene, prazosin, and triamterene were purchased from Sigma-Aldrich (St. Louis, MO). 4′-Hydroxy PhIP (4′-OH PhIP) was a gift from Dr. Hitoshi Nakagama (Biochemistry Division, National Cancer Center Research Institute, Tokyo, Japan). All other chemicals were commercially available and of reagent grade. Male wild-type FVB mice and Mdr1a-expressing LLC-PK1 cells (L-Mdr1a). L-Mdr1a and parent LLC-PK1 cells were seeded in a 24-well Transwell at a density of 4.8 × 104 cells/well and Bcrp-expressing cells (MDCK II/GFP and MDCK II/Bcrp, respectively) were used for transport studies. The cells were preincubated in Krebs-Henseleit bicarbonate (pH 7.4) buffer for 30 min, and transport experiments were initiated by replacing the medium on one side of the cell monolayer with Krebs-Henseleit buffer containing 3 μM test compounds. At appropriate times (20, 40, and 60 min), 100-μl aliquots were taken from the opposite side of the cell monolayer and replaced with 100 μl of buffer. In vitro transport experiments of mouse Mdr1a were carried out using Mdr1a-expressing LLC-PK1 cells (L-Mdr1a). L-Mdr1a and parent LLC-PK1 cells were seeded in a 24-well Transwell at a density of 4.8 × 104 cells/well and grown in medium 199 (Invitrogen, Carlsbad, CA) with 10% fetal bovine serum (Sigma-Aldrich) and 1% antibiotic-antimycotic solution (Sigma-Aldrich). The cells were infected with the recombinant adenosine harboring green fluorescent protein (GFP) or mouse Bcrp expression vector at a 200 multiplicity of infection. The details of the construction of these recombinant adenosines are described in a previous report (Kondo et al., 2004). After a 2-day culture, both GFP- and Bcrp-expressing cells (MDCK II/GFP and MDCK II/Bcrp, respectively) were used for transport studies. The cells were preincubated in Krebs-Henseleit bicarbonate (pH 7.4) buffer for 30 min, and transport experiments were initiated by replacing the medium on one side of the cell monolayer with Krebs-Henseleit buffer containing 3 μM test compounds. At appropriate times (20, 40, and 60 min), 100-μl aliquots were taken from the opposite side of the cell monolayer and replaced with 100 μl of buffer. In vitro transport experiments of mouse Mdr1a were carried out using Mdr1a-expressing LLC-PK1 cells (L-Mdr1a). L-Mdr1a and parent LLC-PK1 cells were seeded in a 24-well Transwell at a density of 4.8 × 104 cells/well and grown in medium 199 (Invitrogen) with 10% fetal bovine serum and 1% antibiotic-antimycotic solution. Medium was changed on the 2nd day, and cells were subjected to the transport study on the 4th day. The procedures for the transport study were the same as those used for mouse Bcrp.

In Vivo Study with Continuous Infusion. Under urethane anesthesia (1.25 g/kg i.p.), the right jugular vein of the mouse was cannulated with a polyethylene tube (PE-10; BD Biosciences, Franklin Lakes, NJ). Compounds were administered via i.p. injection of pentobarbital sodium (50 mg/kg), and the right common carotid artery was catheterized with a polyethylene tube (PE-10) mounted on a 30-gauge needle. Before insertion of the catheter, the common carotid artery was ligated caudally. During surgery, the body temperature was maintained on a heated plate. The syringe containing the perfusion fluid was placed in an infusion pump (PerkinElmer Life and Analytical Sciences, Morden, CT) and connected to the catheter. Before perfusion, the thorax of the animal was opened, the heart was cut, and perfusion was started immediately at a flow rate of 1 ml/min. The perfusion fluid consisted of Krebs-Henseleit bicarbonate buffer: 25 mM NaHCO3, 118 mM NaCl, 4.7 mM KCl, 1.2 mM MgSO4, 1.2 mM NaH2PO4, 1.2 mM CaCl2, and 10 mM d-glucose. The perfusion fluid was gassed with 95% O2 and 5% CO2 for pH control (7.4) and warmed to 37°C in a water bath. The concentration of the test compounds was 5 μM. The 1-min perfusion was terminated by decapitation. The brain was then removed, and the cortex of the right cerebral hemisphere was collected and weighed.

Calculation of Initial Uptake Clearance. The average vascular volume (Vv) following brain perfusion is reported to be 10 μl/g brain (Dagenais et al., 2000). This value was used to correct for vascular contamination in brain tissue. The initial uptake clearances of test compounds (Clu) (microliters per minute per gram of brain) were calculated using the equation: Clu = Xbrain/ Vv T perf, where Xbrain is the compound in the right cortex (nanomoles per gram of brain) corrected for vascular contamination (Xtotal – Vv X uptake/x perf). T perf is the concentration of compound in the perfusate (nanomoles per microliter), and T is the perfusion time (minutes).

In Vitro Transport Study. In vitro transport experiments of mouse Bcrp were performed as previously reported with minor modifications (Matsushima et al., 2005). Briefly, MDCK II cells were seeded into a 24-well Transwell (Corning, Cambridge, MA) at a density of 1.4 × 105 cells/well and grown for 3 days in Dulbecco’s modified Eagle’s medium (Invitrogen, Carlsbad, CA) with 10% fetal bovine serum (Sigma-Aldrich) and 1% antibiotic-antimycotic solution (Sigma-Aldrich). The cells were infected with the recombinant adenosine harboring green fluorescent protein (GFP) or mouse Bcrp expression vector at a 200 multiplicity of infection. The details of the construction of these recombinant adenosines are described in a previous report (Kondo et al., 2004). After a 2-day culture, both GFP- and Bcrp-expressing cells (MDCK II/GFP and MDCK II/Bcrp, respectively) were used for transport studies. The cells were preincubated in Krebs-Henseleit bicarbonate (pH 7.4) buffer for 30 min, and transport experiments were initiated by replacing the medium on one side of the cell monolayer with Krebs-Henseleit buffer containing 3 μM test compounds. At appropriate times (20, 40, and 60 min), 100-μl aliquots were taken from the opposite side of the cell monolayer and replaced with 100 μl of buffer. In vitro transport experiments of mouse Mdr1a were carried out using Mdr1a-expressing LLC-PK1 cells (L-Mdr1a). L-Mdr1a and parent LLC-PK1 cells were seeded in a 24-well Transwell at a density of 4.8 × 104 cells/well and grown in medium 199 (Invitrogen) with 10% fetal bovine serum and 1% antibiotic-antimycotic solution. Medium was changed on the 2nd day, and cells were subjected to the transport study on the 4th day. The procedures for the transport study were the same as those used for mouse Bcrp.

Efflux rates were calculated from the slopes of the time profiles of the apical-to-basal and basal-to-apical transport. Flux ratios were obtained by dividing efflux rates in the basal-to-apical direction by those in the apical-to-basal direction. Flux ratios in transporter-expressing cells were divided by those in control cells to give a CFR. CFR was used as the transport activity index.

Preparation of N-OH PhIP. After the administration of PhIP to rats, N-OH PhIP is excreted into the bile mainly in its glucuronide form (Dietrich et al., 2001). Therefore, N-OH PhIP was purified from β-glucuronidase-treated bile obtained from rats that had been given PhIP. Under ether anesthesia, the bile duct was cannulated with a polyethylene tube (PE-10), then PhIP was i.p. administered at a dose of 100 mg/kg, and bile was collected for 2.5 h. Bile was loaded onto a solid-phase extraction cartridge (OASIS HLB; Waters, Milford, MA), which was then washed with water and eluted with acetonitrile. The eluted solution was evaporated, reconstituted in PBS containing 5 mM ascorbic acid, and treated with β-glucuronidase (Roche Diagnostics, Basel, Switzerland) for 3 h at 37°C. Ascorbic acid was added to prevent the autooxidation of N-OH PhIP. The reaction was stopped by adding a 30% volume of acetonitrile, and N-OH PhIP was purified by HPLC, using a D-7000 series instrument.
(Hitachi, Tokyo, Japan) equipped with an Inertsil ODS-2, 5 μm, 4.6-mm i.d. × 250-mm column (GL Science, Tokyo, Japan). The mobile phase A was 10 mM ammonium acetate, and the mobile phase B was acetonitrile. The mobile phase B concentration was 7% at 0 min and was then linearly increased to 20% over 60 min followed by a 5-min re-equilibration with the initial concentration. The flow rate was 1.2 ml/min, the column temperature was 40°C, and the detector wavelength was 313 nm. Under these conditions, PhIP, 4'-OH PhIP, and prazosin were significantly increased in Bcrp<sup>−/−</sup> mice in comparison with those in wild-type mice for PhIP, N-OH PhIP, MelQx, dantrolene, and prazosin. For 4'-OH PhIP, the brain concentrations of 4'-OH PhIP were below the limit of quantification (15 nm) in both wild-type and Bcrp<sup>−/−</sup> mice, whereas <i>K<sub>p,brain</sub></i> exhibited a significant increase in Bcrp<sup>−/−</sup> mice. For triamterene, both the <i>K<sub>p,brain</sub></i> and <i>K<sub>p,testis</sub></i> values were increased in Bcrp<sup>−/−</sup> mice; however, only the increase in the <i>K<sub>p,brain</sub></i> was statistically significant.

**Effect of Bcrp on Uptake Transport in the BBB.** The effect of functional impairment of Bcrp on the brain uptake was investigated by the in situ brain perfusion technique for PhIP, dantrolene, and daidzein. In all cases, a relatively large increase in the <i>K<sub>p,brain</sub></i> values was observed in Bcrp<sup>−/−</sup> mice. Significant increases in <i>Cl<sub>Lp</sub></i> were observed in Bcrp<sup>−/−</sup> mice for dantrolene and daidzein (Fig. 3). The increase was 2.1-fold for dantrolene and 1.4-fold for daidzein. The <i>Cl<sub>Lp</sub></i> of PhIP was not significantly changed in Bcrp<sup>−/−</sup> mice.

**In Vitro Transport by Mouse Bcrp and Mdr1a and a Comparison with in Vivo Data.** Transcellular transport of the compounds was examined in polarized cell lines expressing Bcrp and Mdr1a where Bcrp and Mdr1a are localized in the apical membrane (Yamazaki et al., 2001; Matsushima et al., 2005). In Bcrp-expressing cells, all the test compounds exhibited directional transport with statistically significant changes in the permeability (Fig. 4, Table 2), indicating that all the compounds are Bcrp substrates. The comparison between <i>K<sub>p</sub></i> ratios and CFR values in Bcrp-expressing cells is shown in Fig. 5 and Table 3. The data of three phytoestrogens were taken from our previous study (Enokizono et al., 2007b). The relationships did not show any positive correlation (Fig. 5). Although PhIP, MelQx, prazosin, and triamterene exhibited large CFR values, the effect of functional impairment of Bcrp on the tissue concentration was marginal.

The time profiles in the transcellular transport in Mdr1a-expressing cells are shown in Fig. 6 and Table 2. In Mdr1a-expressing cells, directional transport across the cell monolayers was clearly enhanced for MelQx, PhIP, and prazosin, and apical-to-basal transport was significantly reduced for triamterene (Table 2). No significant change was observed for dantrolene (Table 2). Therefore, MelQx, PhIP, prazosin, and triamterene are Mdr1a substrates, whereas dantrolene is not. PhIP, MelQx, prazosin, and triamterene, which exhibited a marginal increase in the <i>K<sub>p</sub></i> ratios, were all common substrates of Bcrp.

The rates of 20
drug compounds were basic or neutral at physiological pH.

The increase in the

Kp values in the brain
dehydroxylation products were Bcrp-specific substrates. The most acidic and basic pKp values are shown in Table 3. The four BCRP-selective compounds were all weak acids, whereas the other compounds were basic or neutral at physiological pH.

**Discussion**

In the present study, the effects of BCRP on the brain and testicular distribution of two dietary carcinogens and three drugs were investigated using Bcrp−/− mice. The increase in the Kp values in the brain and testis in Bcrp−/− mice compared with wild-type mice indicates that Bcrp limits both the brain and testicular distribution of MeIQx, PhIP, N-OH PhIP, dantrolene, and prazosin. For triamterene, the Kp,brain was significantly increased in Bcrp−/− mice, whereas the Kp,testis was increased, but this was not statistically significant. For 4′-OH PhIP, Kp,testis was significantly increased in Bcrp−/− mice, whereas its brain concentration was below the limit of quantification; thus, the impact of functional impairment of Bcrp on the Kp,brain of 4-OH PhIP remains to be evaluated. In contrast, the impact of functional impairment of Bcrp on the uptake transport in the BBB was
smaller than that observed on the $K_p$ values (Fig. 3). Because the $K_p$ values determined under steady-state conditions represent the ratio of the clearance of uptake transport to that of efflux transport, it is likely that Bcrp mainly influences the efflux transport of its substrates in the BBB. The increase in the $K_p,\text{brain}$ of prazosin in Bcrp−/− mice is consistent with a previous study in which the brain concentration of prazosin was increased by coadministration of GF120918 in Mdr1a−/− mice (Cisternino et al., 2004). The present results on PhIP contradict a previous study in which neither $K_p,\text{brain}$ nor $K_p,\text{testis}$ was changed (van Herwaarden et al., 2003). This discrepancy can be explained by the difference in the method of determining the plasma and tissue concentrations. van Herwaarden et al. (2003) determined the total radioactivities in the plasma and tissues without separation, whereas in the present study, the parent drug and metabolites were separately determined by LC/MS/MS. Indeed, the total radioactivity associated with plasma specimens was mainly associated with unknown metabolites, other than the metabolites 4'-OH and N-OH PhIP, when 14C-PhIP was given to mice (data not shown). It is possible that the metabolites in the plasma made it difficult to detect an increase in the brain and testicular distribution of PhIP in Bcrp−/− mice.

The in vivo Bcrp activities (expressed as $K_p$ ratios) were compared with the in vitro transport activities by Bcrp (expressed as CFR) estimated using a cell line expressing mouse Bcrp. Previously, Adachi et al. (2001) and Yamazaki et al. (2001) demonstrated clear positive relationships between the $K_p$ ratios and CFR for Mdr1a. Unlike the case of Mdr1a, the in vivo and in vitro Bcrp activities did not show a positive relationship. The Bcrp substrates with a greater CFR exhibited a somewhat smaller increase in $K_p$ values (Fig. 5). We assumed

FIG. 3. Comparison of the uptake clearances ($CL_{up}$) in the BBB between wild-type and Bcrp−/− mice. The brain uptake for 1 min was determined by the in situ brain perfusion technique. $CL_{up}$ was obtained by subtracting the amount associated with the capillary space from that associated with brain specimens divided by the concentration in the infusate. $CL_{up}$ values in wild-type and Bcrp−/− mice are represented by closed and open bars, respectively. Each bar with an error bar represents the mean value and S.E. obtained from three or four mice. Asterisks represent statistically significant differences between wild-type and Bcrp−/− mice: *, $P<0.05$ and **, $P<0.01$.

FIG. 4. Transcellular transport across MDCKII cell monolayers expressing GFP (MDCKII/GFP) or mouse Bcrp (MDCKII/Bcrp). The transcellular transport of test compounds ($3\mu M$) in the apical-to-basal (circles) and basal-to-apical directions (triangles) was compared between MDCKII/GFP (closed symbols with dotted line) and MDCKII/Bcrp cells (open symbols and solid line). Each symbol with a bar represents the mean value and S.E. of triplicate experiments.
that this discrepancy is accounted for by the difference in the contribution of Bcrp to the net efflux at the BBB and BTB. Indeed, it was found that some Bcrp substrates are also P-gp substrates. In particular, the compounds exhibiting large increases in \( K_p \) ratios were Bcrp-specific substrates. Therefore, it is likely that, for common substrates of Bcrp and P-gp, the impact of functional impairment of Bcrp on the \( K_p \) values becomes smaller than predicted from the CFR because of active efflux mediated by P-gp. This will also account for the discrepancy reported previously that the brain distribution of some Bcrp substrates, such as fluorquinolones, mitoxantrone, and pitavastatin, was unchanged in Bcrp \(^{-/-} \) mice (Hirano et al., 2005; Lee et al., 2005; Ando et al., 2007). All these compounds are also substrates of P-gp (de Lange et al., 2000; Yagi et al., 2003; Sasabe et al., 2004; Hirano et al., 2005), and the brain distributions of mitoxantrone, grepafloxacin, and ulifloxacin were significantly increased in Mdr1a/b \(^{-/-} \) mice (Yagi et al., 2003; Sasabe et al., 2004). As far as DHEAS is concerned, the \( \text{Cl}_{\text{ap}} \) of DHEAS in the brain was not increased in Mdr1a/b \(^{-/-} \) mice (Lee et al., 2005). The reason for the absence of a change in the \( K_p \) values in Bcrp \(^{-/-} \) remains unknown. It is possible that brain perfusion study was not suitable for the detection of the involvement of Bcrp in the transport of DHEAS. It is also possible that other transporters besides Bcrp and P-gp are involved in the transport of DHEAS in the BBB. A candidate transporter is MRP4, which is expressed on the luminal side of BMECs (Leggas et al., 2004) since DHEAS is a substrate of MRP4 (Bai et al., 2004).

The four Bcrp-specific substrates are weak acids, whereas the other compounds are basic or neutral at physiological pH (Table 3). P-gp is well characterized by its preferential substrate recognition of lipophilic and basic compounds. BCRP also recognizes basic compounds, such as cimetidine and imatinib (Burger et al., 2004; Breedveld et al., 2005), but it also accepts acidic compounds, such as methotrexate and sulfate conjugates (Volk et al., 2002; Suzuki et al., 2003). Based on the substrate specificity, it was speculated that BCRP plays a major role in the efflux of acidic compounds in the BBB and BTB, but only a limited role in the efflux of basic compounds, which are mainly extruded by P-gp. It should be noted that some MRPs have been identified in the BBB, which accepts anionic compounds as substrates (Kusuha et al., 1998; Zhang et al., 2000; Leggas et al., 2004). Further studies are necessary to elucidate the role of Bcrp in the BBB.

Dietary carcinogens, such as PhIP, 2-amino-3-methylimidazo[4,5-f]quinoline, and 3-amino-1,4-dimethyl-5H-pyrido[4,3-b]indole, have been identified as BCRP substrates (van Herwaarden et al., 2006), and MelQxs was identified as a BCRP substrate for the first time in the present study. Schinkel and his collaborators (van Herwaarden et al., 2003, 2006; Jonker et al., 2005) demonstrated the involvement of BCRP in the oral availability, milk secretion, biliary, and intestinal excretion of dietary carcinogens. In addition, the present study revealed that BCRP limits penetration of dietary carcinogens into the brain and testis. N-Hydroxylation is a bioactivation pathway for dietary carcinogens (Kim and Guengerich, 2005). Our results suggest that Bcrp accepts N-OH PhIP; moreover, BCRP may limit DNA adduct formation in the brain and testis.

The plasma concentrations of PhIP, 4′-OH PhIP, and prazosin were slightly, but significantly, lower in Bcrp \(^{-/-} \) mice, suggesting induction of some clearance mechanisms for these substrates in Bcrp \(^{-/-} \) mice. Previously, we reported the induction of compensatory mechanisms for the elimination of troglitazone sulfate from the systemic circulation in Bcrp \(^{-/-} \) mice (Enokizono et al., 2007a). The underlying mechanisms remain unknown. Further studies are required to investigate such compensatory mechanisms in Bcrp \(^{-/-} \) mice.

In conclusion, the present study revealed that BCRP limits the brain and testicular distribution of MelQx, PhIP, prazosin, triamterene, and dantrolene. Because of the overlapping substrate specificities of Bcrp...
and P-gp. P-gp is also involved in the efflux of some Bcrp substrates at the BBB, thereby modulating the impact of functional impairment of BCRP.

Acknowledgments. We thank Hitoshi Nakagama (Biochemistry Division, National Cancer Center Research Institute) for supplying 4′-OH PhIP and Junko Iida and Futoshi Kurotobi (Shimadzu) for technical support of the LC/MS system.
