ABSTRACT:

There is growing clinical interest of thalidomide because of its immunomodulatory and antiangiogenic properties, despite its teratogenicity. However, little information about thalidomide has been reported regarding its precise effects on drug-metabolizing enzymes. We investigated the effects of thalidomide on cytochrome P450 (P450) enzymes in human liver microsomes to clarify the potential for possible drug interactions. Thalidomide inhibited S-mephenytoin 4′-hydroxylation activities of recombinant P450 2C19 and human liver microsomes: the apparent concentration of thalidomide producing 50% inhibition was approximately 270 μM for P450 2C19. Midazolam 4-hydroxylation activities were suppressed by thalidomide, but activities of 1′-hydroxylation and total midazolam oxidation and testosterone 6β-hydroxylation were enhanced in the presence of thalidomide. Recombinant P450 3A5 was found to have altered kinetics at clinically relevant concentrations of thalidomide (10–30 μM). P450 3A4 was also affected, but only at higher thalidomide concentrations. Enhanced midazolam hydroxylation by thalidomide was also seen in liver microsomal samples harboring the CYP3A5*1 allele. Similarly enhanced rates of cyclosporine A clearance were observed in P450 3A5 and liver microsomes expressing P450 3A5 in the presence of thalidomide. A proposed effector constant for thalidomide corresponded roughly to its clinical plasma levels. Docking studies with a P450 3A5 homology model, based on the published structure of P450 3A4, revealed close interaction between thalidomide and the heme of P450 3A5. The present results suggest that total midazolam metabolism or cyclosporine A clearance may be increased by thalidomide in a dose-dependent manner. Unexpected drug interactions involving thalidomide might occur via heterotropic cooperativity of polymorphic P450 3A5.

Cytochrome P450 (P450) comprises a superfamily of enzymes involved in the oxidation of a large number of endogenous and exogenous compounds (Guengerich, 2008). In the human liver (HL), P450 3A4 is the major P450 enzyme followed by P450 2C9 (Shimada et al., 1994); however, the importance of polymorphic P450 3A5 in drug oxidations in Asian populations has been recently suggested (Yamaori et al., 2004; Niwa et al., 2008a). P450 2C19 also catalyzes oxidation of many marketed drugs (Williams et al., 2004), and thalidomide has been considered to undergo very little metabolism by the P450 system, at least P450 3A4. However, at least two hydroxylated metabolites of thalidomide have been found in human urine and plasma, both of which could be formed at very low concentrations after incubation with human liver microsomes or recombinant P450 2C19 (Ando et al., 2002). In addition, previous findings have shown spontaneous nonenzymatic hydrolysis (Schumacher et al., 1965). To address the inhibitory potential of a drug, it was considered important to determine an inhibition constant

ABBREVIATIONS: P450, cytochrome P450; HL, human liver.
and an apparently observed (K_i) (Ito et al., 2004). However, there is little information about inhibition by thalidomide thus far.

The purpose of this study was to clarify the inhibitory potential of thalidomide with human P450 enzymes, to understand possible drug interactions. We investigated the effects of thalidomide on P450 activities and found that thalidomide inhibited P450 2C19-dependent S-mephenytoin 4′-hydroxylation at high concentrations but enhanced P450 3A5-dependent midazolam hydroxylation and cyclosporine A clearance at clinically relevant concentrations. Although there are reports on ligand cooperativity with P450 3A5 (Niwa et al., 2008b), we report a proposed effector constant for thalidomide in the heterotrophic cooperativity of P450 3A5 in human liver microsomes, adapting 1 + [I]/K_i treatment theory for drug interaction studies. A proposed model for heterotrophic cooperativity of P450 3A5 is presented.

Materials and Methods

Chemicals. (+)-Thalidomide was purchased from Sigma-Aldrich (St. Louis, MO). Cyclosporine A and midazolam were obtained from Wako Pure Chemicals (Osaka, Japan). Other chemicals and reagents used in this study were obtained from the sources described previously (Yamazaki et al., 2002, 2006) or were of the highest qualities commercially available.

Enzyme Preparations. Human liver microsomes were prepared in 10 mM Tris-HCl buffer (pH 7.4) containing 0.10 mM EDTA and 20% (v/v) glycerol as described previously (Yamazaki et al., 2006). The use of the human livers for this study was approved by the Ethics Committees of Vanderbilt University and Showa Pharmaceutical University. Each recombinant human cytochrome P450, coexpressed in Escherichia coli membranes with human NADPH-P450 reductase, was prepared as described earlier (Yamazaki et al., 2002). Genomic DNA samples from livers were genotyped for the CYP2C19 and CYP3A5 genes as described previously (Inoue et al., 1997; Yamaori et al., 2004).

Enzyme Assays. Midazolam 1′- and 4-hydroxylation activities were determined using high-performance liquid chromatography (Emoto et al., 2008). Cyclosporine A oxidation was determined by the disappearance of parent compound (Dai et al., 2004). In brief, a typical incubation mixture (total volume of 0.25 ml) contained microsomal protein (0.25 mg/ml) or recombinant P450 (0.06 μM), an NADPH-generating system (0.25 mM NADP+, 2.5 mM glucose 6-phosphate, and 0.25 unit/ml glucose 6-phosphate dehydrogenase), and substrate and/or thalidomide in 0.1 M potassium phosphate buffer (pH 7.4), unless otherwise specified. For P450 activity determinations, incubations were performed at 37°C for 10 to 30 min. Incubations were terminated by adding 0.25 ml of ice-cold acetonitrile. The aqueous supernatant was centrifuged at 2000g for 10 min and subjected to high-performance liquid chromatography by using an analytical octadecylsilane (C18) column (4.6 mm × 150 mm, 5 μm).

Ethoxyresorufin O-deethylation, 7-ethoxycoumarin O-deethylation, diclofenac 4′-hydroxylation, S-mephenytoin 4′-hydroxylation, and testosterone 6β-hydroxylation activities were determined as described previously (Yamazaki et al., 2002). Microsomal protein concentrations were estimated by using a bichromonic acid protein assay kit (Pierce, Rockford, IL). Concentrations of total P450 (Omura and Sat0, 1964) and NADPH-P450 reductase (EC 1.6.2.4) (Yamazaki et al., 2002) as well as P450 3A4 and 3A5 contents in liver microsomes (Yamaori et al., 2005) were determined as described previously. The liver microsomal samples HL-1 and HL-3 contained 18 pmol P450 3A4 or P450 3A5 (Yamaori et al., 2005).

Kinetic Analysis. Kinetic analysis was done using nonlinear regression analysis programs [KaleidaGraph (Synergy Software, Reading, PA) and Prism (GraphPad Software Inc., San Diego, CA)] using the following equations. Inhibition by thalidomide (concentration [I]) of midazolam 4-hydroxylation activity (v) of P450 3A as a function of substrate concentration [S] with a maximum velocity (V_{max}) was analyzed for competitive inhibition with the usual eqs. 1 and 2:

\[ v = \frac{V_{max} \cdot [S] \cdot (K_{m,obs} + [S])}{K_{m,obs} + [S]} \]  

and an apparently observed K_m value (K_{m,obs}), namely (eq. 2):

\[ K_{m,obs} = K_m \cdot (1 + [I]/K_i) \]  

where K_m is the inhibition constant (Ito et al., 2004). On the other hand, midazolam 1′-hydroxylation activity (v) shows a substrate-inhibition manner with the eq. 3 formula, including the substrate inhibition constant K_i (Dai et al., 2004):

\[ v = \frac{V_{max} \cdot [S] \cdot (K_{m,obs} + [S])}{K_{m,obs} + [S] + [S]^2/K_i} \]  

When the enzyme activities (v) are increased by thalidomide (concentration [E]), resulting apparent V_{max} values multiplied by [1 + [E]/K_i (effector constant)] or deceased K_{m,obs} divided by (1 + [E]/K_i) are proposed using the eq. 3 formula. In the present study, apparent V_{max} values were not affected, but K_{m,obs} values were decreased in the presence of thalidomide; therefore, eqs. 3 and 4, including a novel parameter for effector concentration K_e, were proposed in this study:

\[ K_{m,obs} = K_m/(1 + [E]/K_e) \]

Docking Simulation of Thalidomide into Reported Structure of P450 3A4 and a Homology Model of P450 3A5. The human P450 3A5 primary sequence was aligned with human P450 3A4 (Protein Data Bank code 1TQN) in the MOE software (version 2007.09; Chemical Computing Group, Montreal, Canada) for modeling of a three-dimensional structure (Pearson et al., 2007). Before docking, the energy of the P450 3A4 or 3A5 structure was minimized using the CHARMM22 force field. Docking simulations were carried out for thalidomide binding to the reported P450 3A4 or a homology model of P450 3A5 using the MMFF94x force field distributed in the MOE Dock software. Twenty solutions were generated for each docking experiment and ranked according to total interaction energy (S value).

Results

Inhibitory or Enhancing Effects of Thalidomide on Activities of Human P450 Enzymes. Because P450 2C19 has already been shown to be the major enzyme involved in the oxidative metabolism of thalidomide (Ando et al., 2002), we first investigated the inhibitory effects of thalidomide on the typical marker activities of a series of P450 enzymes. The oxidation activities measured with the substrates ethoxyresorufin (10 μM) (recombinant P450 1A1 and 1A2), 7-ethoxycoumarin (100 μM) (recombinant P450 2B6), and diclofenac (50 μM) (recombinant P450 2C9) were not affected by thalidomide (up to 500 μM) under these conditions (results not shown). P450 2C19 S-mephenytoin 4′-hydroxylation activity was suppressed by thalidomide in a concentration-dependent manner (Fig. 1A); 50% inhibition was observed with a thalidomide concentration of 270 μM. Similar inhibitory effects of thalidomide on S-mephenytoin hydroxylase activity were seen in liver microsomal preparations (genotyped as CYP2C19*1/*1) (Fig. 1B).

On the contrary, testosterone 6β-hydroxylation (Fig. 2, A and B) by P450 3A4 or P4503A5 was enhanced by thalidomide. Midazolam 1′-hydroxylation activities (Fig. 2D) of P450 3A5 were highly enhanced in the presence of low concentrations of thalidomide. These activities were less affected by thalidomide with P450 3A4 than P450 3A5 (Fig. 2C). The minor pathway, midazolam 4-hydroxylation, was slightly suppressed by thalidomide (with P450 3A4 or 3A5), but rates of formation of the major product (1′-hydroxylation) and total oxidative products of midazolam were stimulated in the presence of thalidomide.

Modifications of Kinetic Parameters for P450 3A-Dependent Drug Oxidation Activities by Thalidomide. It was of interest to describe the enhancing effects of thalidomide in terms of an effector concentration. Midazolam 1′- and 4-hydroxylation activities were plotted against substrate concentrations in the presence of various concentrations of thalidomide (Fig. 3). Only small effects of thalidomide on the midazolam hydroxylation activities of P450 3A4 were observed (Fig. 3A). In the contrast, midazolam 1′-hydroxylation activities of P450 3A5 at low substrate concentrations were enhanced in...
midazolam (100 μM) was incubated with P450 2C19 and human liver microsomal sample HL-1 (genotyped as CYP2C19*1/*1) in the absence or presence of thalidomide. Results are presented as means and ranges of duplicate determinations.

Testosterone 6β-hydroxylation activities in liver microsomal samples HL-3 (C) and HL-1 (D) were genotyped as CYP3A5*3/*3 and CYP3A5*1/*3, respectively. Results are presented as means of duplicate determinations.

Midazolam 1'- and 4-hydroxylation activities were not extensively affected, as in the case of recombinant P450 3A5 (Fig. 3B). We adopted a new parameter, $K_{\text{e}}$, for modified $K_{\text{m,obs}}$ values as $K_{\text{m}}(1 + [E]/K_{\text{e}})$, in the same way as $K_{\text{e}}$ for $K_{\text{m,obs}}(1 + [I]/K_{\text{i}})$ (Table 1). The $K_{\text{e}}$ value of thalidomide enhancement of midazolam 1'-hydroxylation catalyzed by recombinant P450 3A5 was calculated to be 40 ± 7 μM. Similar reduced $K_{\text{m,obs}}$ values for midazolam 1'-hydroxylation activities by increasing concentrations of thalidomide were obtained in the human liver microsomes expressing P450 3A5 protein (CYP3A5*1/*3): the $K_{\text{e}}$ value was 62 ± 24 μM using the equation of $K_{\text{m,obs}} = K_{\text{m}}(1 + [E]/K_{\text{e}})$. In the case of P450 3A4, >10-fold higher $K_{\text{e}}$ values of thalidomide were obtained (Table 1).

To confirm the enhancing effects of thalidomide on liver microsomal P450 3A5, the oxidation of cyclosporine A was also used as a test reaction (Fig. 4). P450 3A4-catalyzed cyclosporine A oxidation was not affected by thalidomide (Fig. 4A). P450 3A5-catalyzed cyclosporine A oxidation (substrate concentrations of 2 and 10 μM) was enhanced by increasing concentrations (2–30 μM) of thalidomide (Fig. 4B). Similar enhancement of cyclosporine A oxidation by thalidomide was observed in liver microsomes expressing P450 3A5 and 3A4 (Fig. 4D) but not in other liver microsomes mainly expressing P450 3A4 (Fig. 4C). Thalidomide (10–30 μM) enhanced cyclosporine A oxidation mediated by P450 3A5 in human liver microsomes approximately 2-fold.

Docking Simulation of Thalidomide into P450s 3A4 and 3A5.

The human P450 3A4 crystal structures allowed generation of a homology model of P450 3A5 using the MOE program. The top-rank docking model of thalidomide in P450 3A4 or 3A5 was adopted. In the P450 3A4 model, the aromatic ring of thalidomide was found far from the heme of P450 3A4 (Fig. 5A). In contrast, in the P450 3A5 model, the cycloalkane ring of thalidomide was closely orientated to the center of the heme of P450 3A5 (Fig. 5B).

**Discussion**

In the course of screening the inhibitory potential of thalidomide with human P450 enzymes, thalidomide inhibition of P450 2C19-mediated activity and enhancement of P450 3A activities were seen (Figs. 1 and 2). Thalidomide inhibited P450 2C19-dependent...
S-mephenytoin 4′-hydroxylation activity only at high concentrations but enhanced P450 3A5-dependent midazolam 1′-hydroxylation activity at low concentrations. P450s 2C9 and 2C19 have both been shown to have a smaller substrate pocket than P450 3A4 (Yano et al., 2004; Locuson and Wahlstrom, 2005; Ahlström and Zamora, 2008). The thalidomide inhibition constant for P450 3A5 is 83% identical to P450 3A4 and 3A5 models were performed (Fig. 5). Thalidomide could closely dock to the P450 3A5 heme region in silico analysis (Fig. 5B). These results and findings may be collectively relevant to a different preferable substrate orientation for P450 3A5, explaining the P450 3A5 activation.

This activation phenomenon is generally termed heterotropic cooperativity, involving two different ligands in the active site of a P450 enzyme (McConn et al., 2004; Isin and Guengerich, 2006). A proposed model for heterotropic cooperativity of P450 3A5 is shown in Fig. 5C. When thalidomide docks near the heme iron and/or suitable substrate binding area (Roberts and Atkins, 2007; Skopalík et al., 2002). Lys212 of P450 3A5 seems to have a similar property, corresponding to the P450 3A5 heme recognition site. Polymeric P450 3A5s have been suggested to contribute as much as 50% of the liver P450 3A in one third of white and one half of African-Americans (Kuehl et al., 2001; Koch et al., 2002) or Japanese (Yamane et al., 2004). Because P450 3A5 is 83% identical to P450 3A4, it is generally believed that the substrate specificity of P450 3A5 is similar to that of P450 3A4, although some differences in catalytic properties have been found (Daly, 2006; Niwa et al., 2008a,b). Less activation of P450 3A4 by thalidomide was observed under our conditions. On the other hand, midazolam 4-hydroxylation (minor pathway) was inhibited but 1′-hydroxylation and total disappearance of midazolam (as well as cyclosporine A) were enhanced by thalidomide, presumably mediated via a cooperativity mechanism in P450 3A5 (Figs. 3 and 4). In our preliminary experiments, preincubation of thalidomide with P450 3A5 in the presence of NADPH resulted in decreases in enhanced midazolam 1′-hydroxylation (results not shown), suggesting the involvement of thalidomide itself, not a product (tentatively 5′-hydroxythalidomide), in the activation. Similar activation of P450 3A5-mediated midazolam 1′-hydroxylation was also observed in another liver microsomal sample, HL-130, harboring CYP3A5*1/*3 but not in HL-127 (CYP3A5*3/*3) (results not shown). Because the apparent K_{m} values for midazolam 1′-hydroxylation in recombinant P450 3A5 and human liver microsomes were similarly decreased in the presence of thalidomide, the proposed K_{c} values of thalidomide (approximately 40 μM) for P450 3A5 and liver microsomes are consistent and are one order of magnitude less than those for P450 3A4 (Table 1). These results suggest the hypothesis that thalidomide preferentially binds to P450 3A5. To further address this hypothesis, docking simulations of thalidomide into P450 3A4 and 3A5 models were performed (Fig. 5). Thalidomide could closely dock to the P450 3A5 heme region in silico analysis (Fig. 5B). These results and findings may be collectively relevant to a different preferable substrate orientation for P450 3A5, explaining the P450 3A5 activation.

This activation phenomenon is generally termed heterotropic cooperativity, involving two different ligands in the active site of a P450 enzyme (McConn et al., 2004; Isin and Guengerich, 2006). A proposed model for heterotropic cooperativity of P450 3A5 is shown in Fig. 5C. When thalidomide docks near the heme iron and/or suitable substrate binding area (Roberts and Atkins, 2007; Skopalík et al., 2002). Lys212 of P450 3A5 seems to have a similar property, corresponding to the P450 3A5 heme recognition site.
conformation, such that the proximal binding niche exists near the heme, leading to the stimulation of the cyclosporine and midazolam oxidative activation observed in the present study.

In terms of the clinical consequences of drug interactions with thalidomide, the present results suggest that a more rapid drug clearance might be due to thalidomide via a P450 3A5 contribution. The reported plasma concentrations of thalidomide (Vogelsang et al., 1992) are similar to the proposed \( K_e \) constants estimated in the present study. Adapting the \( 1/(1+[I]/K_i) \) theory to the \( 1/(1+[E]/K_e) \) equation, thalidomide concentrations could reach levels similar to calculated \( K_e \) constant and, in principal, approximately 1.5-fold enhanced elimination of other drugs mediated by P450 3A5. We propose the \( K_e \) value as a general constant, whereas it is highly likely to be dependent upon an exact pairing of effector and substrate. Vincristine has been reported to be a P450 3A5 substrate (Dennison et al., 2007). Therefore, we investigated interactions between thalidomide and vincristine in vitro. In preliminary experiments, however, low concentrations of thalidomide did not activate the oxidative cleavage of vincristine (catalyzed by P450 3A5 or liver microsomes with CYP3A5*1/*3) (results not shown). The \( K_m \) values (for the major oxidative cleavage of vincristine catalyzed by P450 3A5) have been reported to be 13 to 17 \( \mu M \) (Dennison et al., 2006). Because vincristine is a large molecule and has high P450 3A5 affinity, these present results may be interpreted that thalidomide could not dock in P450 3A5 before vincristine.

In conclusion, the present study suggests that total midazolam metabolism or cyclosporine clearance may be increased by thalidomide with clinical relevant concentrations through the heterotropic cooperativity of human P450 3A5. Because of the high frequency of polymorphic P450 3A5 expression in Asians and Africans, a relatively high frequency of unexpected drug interactions involving thalidomide might occur via P450 3A5 contribution in drug metabolism.

Acknowledgments. We thank Kana Horiuchi and Sachiko Wakiya for assistance.
