Short Communication

Effect of Glucagon-Like Peptide 2 on Hepatic, Renal, and Intestinal Disposition of 1-Chloro-2,4-dinitrobenzene

Received December 16, 2011; accepted March 27, 2012

ABSTRACT:

The ability of the liver, small intestine, and kidney to synthesize and subsequently eliminate dinitrophenyl-S-glutathione (DNP-SG), a substrate for multidrug resistance-associated protein 2 (Mrp2), was assessed in rats treated with glucagon-like peptide 2 (GLP-2, 12 μg/100 g b.w.t. s.c. every 12 h for 5 consecutive days). An in vivo perfused jejunum model with simultaneous bile and urine collection was used. A single intravenous dose of 30 μmol/kg b.wt. 1-chloro-2,4-dinitrobenzene (CDNB) was administered, and its conjugate, DNP-SG, and dinitrophenyl cysteinyl glycine (DNP-CG), resulting from the action of γ-glutamyltransferase on DNP-SG, were determined in bile, intestinal perfusate, and urine by high-performance liquid chromatography. Tissue content of DNP-SG was also assessed in liver, intestine, and kidneys. Biliary excretion of DNP-SG+DNP-CG was decreased in GLP-2 rats with respect to controls. In contrast, their intestinal excretion was substantially increased, whereas urinary elimination was not affected. Western blot and real-time polymerase chain reaction studies revealed preserved levels of Mrp2 protein and mRNA in liver and renal cortex and a significant increase in intestine in response to GLP-2 treatment. Tissue content of DNP-SG detected 5 min after CDNB administration was decreased in liver, increased in intestine, and unchanged in kidney in GLP-2 versus control group, consistent with GLP-2-induced down-regulation of expression of glutathione transferase (GST) Mu in liver and up-regulation of GST-Alpha in intestine at both protein and mRNA levels. In conclusion, GLP-2 induced selective changes in hepatic and intestinal disposition of a common GST and Mrp2 substrate administered systemically that could be of pharmacological or toxicological relevance under therapeutic treatment conditions.

Introduction

Glucagon-like peptide-2 (GLP-2) is a 33-amino acid hormone secreted by L enteroendocrine cells at the distal intestine (L’Heureux and Brubaker, 2001; Drucker, 2002). Its action was first reported in mice in 1996 (Drucker et al., 1996) and consisted of stimulation of intestinal growth and cell proliferation. Several subsequent studies demonstrated that GLP-2 is capable of restoring mucosal integrity, barrier function, and absorption of nutrients in different experimental models of intestinal injury (Brubaker et al., 1997; Scott et al., 1998; Benjamin et al., 2000; Cani et al., 2009). Because of these properties, GLP-2 was proposed as a potential therapeutic agent to restore intestinal function in different human pathologies, including inflammatory bowel diseases (IBD). In the intestine, it is located at the brush-border membrane of the enterocyte. It is mainly expressed in the proximal small intestine and acts coordinately with conjugating enzymes such as glutathione transferase (GST; EC 2.5.1.18) and UDP-glucuronosyltransferase (EC 2.4.1.17) to metabolize and eliminate common substrates into the intestinal lumen (Mottino et al., 2000). We have recently demonstrated in rats that GLP-2 increases the expression of Mrp2 in jejunum in association with increased prevention of mucosal to serosal absorption of 1-chloro-2,4-dinitrobenzene (CDNB) as an increased amount of its glutathione derivative, dinitrophenyl-glutathione (DNP-SG), is pumped back to the luminal side (Villanueva et al., 2010). The stimulatory effect of GLP-2 was exerted on both GST and Mrp2 and was associated with increased capability for protection against absorption of potentially toxic xenobiotics from the lumen and for prevention of enterocyte...
toxicity. We proposed these findings to be of pathophysiologically relevance as GLP-2 may exert a cytoprotective action under conditions of intestinal damage or during development, lactation, or tissue regeneration in addition to its trophic action. This important role in regulation of membrane chemical barrier gives additional support to therapeutic application of GLP-2 in human intestinal disease.

GLP-2 is normally secreted by the distal intestine, and its action is probably restricted to the digestive tract, mostly to the proximal small intestine, whereas in patients, GLP2 or [Gly2]GLP-2 is preferentially administered subcutaneously (Thulesen et al., 2000; Marier et al., 2008, 2010; Buchman et al., 2010; Jeppesen et al., 2011). Thus, an effect on major epithelial tissues other than the intestine cannot be ruled out under therapeutic treatment conditions. Patients receiving GLP-2 exhibit alterations in intestinal morphology, absorption, and immunological status, and in consequence, they usually receive nutrients and medications parenterally. Thus, the absence of presystemic clearance would give the liver and kidneys a more relevant participation in drug disposition than following oral administration. The effect of subcutaneous administration of GLP-2 on hepatic and renal-conjugating enzymes and Mrp2 has never been explored. In addition, although our previous study demonstrated that GLP-2 improved the ability of the jejunum to restrict absorption of luminal xenobiotics, it remains uncertain whether GLP-2 would similarly improve the elimination of xenobiotics after their systemic administration. In the current study, we explored the effect of GLP-2 on hepatic, renal, and intestinal excretion of DNP-SG after in vivo intravenous single-shot administration of CDNB. Because of the relevance of GST in converting CDNB to the Mrp2 substrate, DNP-SG, we also determined GST activity in cytosol from these tissues. Expression of Mrp2 and major classes of GST were additionally assessed to establish a potential correlation with functional findings. The data show that biliary excretion of DNP-SG was decreased, whereas intestinal excretion was increased by GLP-2. Changes in expression of GST in liver and of cytosol preparations was measured using bovine serum albumin as a standard (Lowry et al., 1951).

Assessment of Expression of Mrp1, Mrp2, Mrp3, and Major GST Classes. Expression of basolateral Mrp1 and Mrp3 proteins was assessed by Western blotting in liver crude plasma membranes and in jejunal- and renal-cortex-solubilized homogenates using goat polyclonal antibodies to human Mrp1 (Santa Cruz Biotechnology, Inc., Santa Cruz, CA) and Mrp3 (Santa Cruz Biotechnology, Inc.). Detection of apical Mrp2 was performed in liver crude plasma membranes and in intestinal and renal brush-border membranes using a monoclonal antibody to human Mrp2 (M2 III-6; Alexis Biochemicals, Carlsbad, CA). Western blot studies of the different GST classes were performed in cytosolic fractions using goat antiserum against rat GST-Alpha and -Mu (GS9 and GS23, respectively; Oxford Biomedical Research, Oxford, MI) and rabbit antiserum against human GST-Pi (Immunootech, Marseille, France) as described previously (Catania et al., 2000). Equal loading and transfer of protein were checked by detection of β-actin using a monoclonal antibody to rat β-actin (Sigma-Aldrich) and by Ponceau S staining of the membranes. The immunoreactive bands were quantified with the Gel-Pro Analyzer (MediaCybernetics, Inc., Bethesda, MD) software.

Quantitative real-time PCR studies of Mrp2 and GST mRNAs were performed as described previously (Villanueva et al., 2010) using the following primer pairs: forward, 5'-acctcaccgctattgct-3' and reverse, 5'-acctctagattgcgcc-3' for Mrp2 (Villanueva et al., 2010); forward, 5'-gattgactcctggag-3' and reverse, 5'-ttgctctgggtgatcttgtg-3' for GSTA1 (Lowry et al., 1962). Protein concentration in plasma membrane, homogenate, and renal cortex homogenates was determined gravimetrically, assuming a density of 1 g/ml. Rat GLP-2 was obtained from American Peptide Company (Sunnyvale, CA).

Animals, Treatment, and Specimen Collection. Adult female Wistar rats weighing 200 to 230 g (National University of Rosario, Rosario, Argentina) were used. Animals had free access to food and water and received human care as outlined in the National Institutes of Health Guide for the Care and Use of Laboratory Animals (Institute of Laboratory Animal Resources, 2010). The rats were randomly divided in two experimental groups. GLP-2-treated rats (GLP-2 group) were administered GLP-2 dissolved in sterile phosphate-buffered saline (PBS) (12 µg/100 g b.wt.) by intraperitoneal injection every 12 h for 5 consecutive days. Control rats (C group) received injections of the vehicle (PBS, subcutaneously) according to this same schedule. Experiments were performed 18 h after the last GLP-2 injection.

The common bile duct was cannulated with polyethylene tubing (PE10) under urethane anesthesia. After a 30-min stabilization period, bile was collected for 10 min in preweighed tubes containing 0.1 ml of 10% sulfosalicylic acid for determination of total and oxidized glutathione and for a further 10 min in dried preweighed tubes to determine the endogenous bilirubin output. Bile flow was determined gravimetrically, assuming a density of 1 g/ml. Immediately after bile collection, animals were sacrificed by exsanguination. The liver was perfused in situ with ice-cold saline through the portal vein and used for preparation of crude plasma membranes by differential centrifugation, as described previously (Meier et al., 1984). The proximal jejunum (~30-cm length) was removed, carefully rinsed with ice-cold saline, and homogenized as described previously (Mottino et al., 2000). Brush-border membranes from the intestinal mucosa were prepared as described previously (Mottino et al., 2000). Renal cortex was isolated and homogenized, and brush-border membranes were obtained by Mg/EGTA precipitation as described previously (Ohoka et al., 1993), with some modifications (Torres et al., 2003). Jejunum and renal cortex homogenates were alternatively solubilized with Triton X-100 as described previously (Cao et al., 2002). Cytosolic fractions from these same tissues were obtained by ultracentrifugation as described previously (Siekevitz et al., 1962). Protein concentration in plasma membrane, homogenate, and cytosol preparations was measured using bovine serum albumin as a standard (Lowry et al., 1951).

Materials and Methods

Chemicals. Leupeptin, phenylmethylsulfonyl fluoride, pepstatin A, succrose, CDNB, and glutathione were obtained from Sigma-Aldrich (St. Louis, MO). Rat GLP-2 was obtained from American Peptide Company (Sunnyvale, CA). All other chemicals and reagents were commercial products of analytical grade purity.

Animals, Treatment, and Specimen Collection. Adult female Wistar rats weighing 200 to 230 g (National University of Rosario, Rosario, Argentina) were used. Jejunum and renal cortex homogenates were alternatively solubilized with Triton X-100 as described previously (Cao et al., 2002). Cytosolic fractions from these same tissues were obtained by ultracentrifugation as described previously (Siekevitz et al., 1962). Protein concentration in plasma membrane, homogenate, and cytosol preparations was measured using bovine serum albumin as a standard (Lowry et al., 1951).
Analytical Procedures. Total glutathione (reduced+oxidized) and oxidized glutathione in bile were determined spectrophotometrically by the recycling method of Tietze (1969), as modified by Griffith (1980). Total bilirubin in bile was determined using a commercial kit (Wiener Lab, Rosario, Argentina) following the manufacturer’s instructions.

Statistical Analysis. Data are presented as mean ± S.D. Statistical analysis was performed using the Student’s t test. Values of P < 0.05 were considered statistically significant.

Results and Discussion

GLP-2 induced a significant increase (+36%) in the weight of the portion of small intestine perfused in vivo relative to body weight compared with controls (0.019 ± 0.002 versus 0.014 ± 0.001, respectively; P < 0.05, n = 4). This portion of the small intestine (−50-cm long) corresponds mainly to jejunum where the highest expression and activity of Mrp2 were reported (Gotot et al., 2000; Mottino et al., 2000). In contrast, the relative masses of the liver and the two kidneys (taken together) did not differ between GLP-2 and control rats (0.033 ± 0.002 versus 0.032 ± 0.001 and 0.008 ± 0.001 versus 0.007 ± 0.001 for liver and kidneys, respectively, P > 0.05, n = 4). GLP-2 did not induce any significant change in basal biliary or urinary flows with respect to control group (see Table 1).

DNP-SG and DNP-CG were the major metabolites of CDNB detected in bile, intestinal perfusate, or urine. DNP-SG is a high-affinity, prototypical Mrp2 substrate (Keppler et al., 2000). Because DNP-CG is formed from DNP-SG once it reaches the extracellular compartment, excretion rate of these two derivatives properly estimates Mrp2 activity as measured in vivo. As shown in Fig. 1A, the biliary excretion rate of DNP-SG+DNP-CG was decreased in GLP-2 rats, particularly during the first periods of bile collection, so that their cumulative excretion was significantly decreased (−20%; Fig. 1A, inset). In contrast, intestinal excretory rate was substantially increased by GLP-2, particularly at the excretion peak, and as a result, their cumulative excretion increased by 103% (Fig. 1A, inset). Urinary excretion of these same compounds was not affected by GLP-2 (Fig. 1A). Excretion of DNP-SG+DNP-CG was also calculated as a percentage of the dose of CDNB. Under normal conditions, biliary and urinary routes accounted for elimination of 50 and 10% of the total DNB dose, respectively, with a minor contribution from intestinal excretion (−1%). The contribution of the biliary route was decreased by GLP-2 (−24%, P < 0.05, n = 4), whereas the intestinal counterpart was substantially increased (+240%, P < 0.05, n = 4), and that of the renal route was not affected. Thus, the total amount of DNP-SG+DNP-CG eliminated by the three tissues was lower in the GLP-2 group relative to the control group, indicating that the impaired excretion of DNP-SG+DNP-CG described for the liver was only partially compensated by their exacerbated intestinal excretion.

Metabolism and transport processes, such as those involving sequential participation of GST and Mrp2, affect a wide variety of naturally occurring xenobiotics and therapeutic drugs (Catania et al., 2004). To further explore the bases for changes in excretion of DNP-SG+DNP-CG by the liver and intestine, we assessed the expression of Mrp2 in crude plasma membranes from liver and apical membranes from intestine and renal cortex. Figure 1B shows that neither the liver nor the kidneys exhibited any change in Mrp2 expression in response to GLP-2 administration, as detected by Western blotting. In contrast, intestinal Mrp2 expression was significantly increased in GLP-2 versus control rats (+75%), in agreement with our previous report (Villanueva et al., 2010). Induction of Mrp2 probably occurred at the transcriptional level, since expression of its mRNA was increased by 123% (P < 0.05, n = 4) in response to GLP-2.

Lever contribution toward DNP-SG elimination was decreased by GLP-2 (Fig. 1A). It is noteworthy that this occurred in spite of preserved expression of Mrp2 in crude plasma membranes. To rule out the possibility of inactivation of Mrp2 in response to GLP-2 treatment, we assessed biliary excretion of glutathione and bilirubin, endogenous substrates with low and high affinities toward Mrp2 (Keppler et al., 2000). The data in Table 1 indicate that neither total nor oxidized glutathione or bilirubin exhibited any changes between GLP-2 and controls. DNP-SG is also a substrate for Mrp1 (Abcc1) and Mrp3 (Abcc3), and their up-regulation at the basolateral membrane of the liver could exacerbate secretion of their substrates into blood, thus influencing their biliary elimination. We found that GLP-2 did not affect the expression of these transporters in any of the tissues studied, either at protein or mRNA levels (data not shown). Furthermore, serum concentration of DNP-SG, detected 5 min after CDNB administration, was not affected by GLP-2 (Table 1). Thus, it seems unlikely that decreased biliary excretion of DNP-SG results from increased transport at the basolateral membrane. Because of its highly hydrophobic nature, it is assumed that CDNB freely enters the cells by diffusion; thus, GST activity becomes the major step determining CDNB conjugation by the different tissues. We found that hepatic GST activity was reduced by 24% in the GLP-2 group (Fig. 2A), in association with reduced expression of GST-Mu (−30%; Fig. 2A), as detected by Western blotting. Thus, an alteration in intrahepatic conjugation of CDNB could be responsible for the impaired hepatic disposition of CDNB shown in Fig. 1A. In support of this possibility, we observed less intrahepatic accumulation of DNP-SG in GLP-2 group than in controls, as detected 5 min after CDNB administration (Table 1). Mrp2-mediated transport, rather than GST conjugation, is the probable rate-limiting step in the overall disposition of CDNB in intestine (Mottino et al., 2001). However, the situation could be different in other tissues with high constitutive Mrp2 expression such as ileum.

* Significantly different from control (C), P < 0.05.
as the liver, where overall transport of DNP-SG could rather depend on its formation, particularly if its subsequent secretion to bile is not saturated. This needs experimental demonstration.

In contrast to GLP-2-induced down-regulation of hepatic GST expression and activity, the rate of intestinal CDNB conjugation was increased (64%) by hormonal treatment, in association with increased expression of GST-Alpha (91%) (Fig. 2B). Consistent with these findings, accumulation of DNP-SG in intestinal tissue was also higher in GLP-2 group (Table 1). GLP-2 was unlikely to affect CDNB conjugation by the kidneys (Table 1), consistent with unaffected levels of GST expression and activity in renal cortex (Fig. 2C).

GSTYb1, GSTYb2, and GSTYa2 are the only isoforms of GST, which belongs to the Mu and Alpha classes, respectively, to be detected in rat liver and intestine (Hayes and Pulford, 1995). GLP-2-induced down-regulation of expression of GST-Mu in liver correlated well with decreased expression of GSTYb1 and GSTYb2 mRNAs (61 and 59%, respectively) compared with controls ($P < 0.05, n = 4$). In contrast, intestinal GSTYa2 mRNA was increased by GLP-2 (121%; $P < 0.05, n = 4$), in agreement with GST-Alpha protein up-regulation (Fig. 2B). Taken together, these data suggest transcriptional regulation of GST-Mu and -Alpha classes by GLP-2.

The up-regulation of intestinal GST expression by GLP-2, in association with up-regulation of Mrp2 expression at the brush-border membrane, could accelerate the inactivation and elimination of toxic compounds absorbed systemically that, as in the case of CDNB, critically depend on sequential participation of biotransformation and transport processes. More importantly, IBD are fairly common chronic inflammatory conditions of the gastrointestinal tract. Although the exact etiology of IBD remains uncertain, reactive oxygen species are produced in abnormally high levels, and their destructive effects may contribute to the initiation and/or propagation of the disease (Rezaie et al., 2007). Because of the known beneficial action of GSTs in detoxifying many electrophilic compounds and fatty acid hydroperoxides, up-regulation of GSTs after GLP-2 treatment could be of clinical relevance in IBD therapy. In line with this, it is noteworthy that patients with ulcerative colitis exhibited deficient

Fig. 1. Effect of GLP-2 on activity and expression of hepatic, intestinal, and renal Mrp2. A, excretion rate of DNP-SG, prototypical substrate for Mrp2, and its derivative DNP-CG was assessed in bile, intestinal perfusate, and urine at 10-, 15-, and 30-min collection periods, respectively, for 90 min. Insets depict cumulative excretion of DNP-SG by 90 min. The data represent means ± S.D. of four rats per group. * significantly different from control (C), $P < 0.05$. B, Mrp2 protein was detected by Western blot of hepatic, intestinal, and renal membranes from GLP-2 and control rats. Protein (5 and 30 μg) from liver crude plasma membranes and brush-border membranes from proximal jejunum and renal cortex, respectively, were loaded in the gels. Uniformity of protein loading and transfer from gel to PVDF membrane was controlled with Ponceau S. Mrp2 expression was normalized relative to β-actin expression; data on densitometric analysis are presented as percentages relative to control, considered as 100%, and were expressed as means ± S.D. of six rats per group. Hepatic GST-Pi was not detected in either control or GLP-2 groups. * significantly different from control (C), $P < 0.05$.

Fig. 2. Effect of GLP-2 on activity and expression of hepatic, intestinal, and renal GST. GST activity toward CDNB (top) and Western blot studies of main GST classes (bottom) were performed in cytosol isolated from liver (A), jejunal mucosa (B), and renal cortex (C). For Western blots, equal amounts of protein (10 μg) were loaded in all lanes. Expression of GST-Alpha, -Mu, and -Pi was calculated relative to β-actin expression. Uniformity of protein loading and transfer from gel to PVDF membrane was controlled with Ponceau S. Data on densitometric analysis are presented as percentages relative to control, considered as 100%, and were expressed as means ± S.D. of six rats per group. Hepatic GST-Pi was not detected in either control or GLP-2 groups. * significantly different from control (C), $P < 0.05$. 1256 VILLANUEVA ET AL.
expression of GST, as detected in serum, which was related to an early age of onset and more severe clinical course, leading to colectomy and increased incidence of colorectal tumors and human normal tissues: potential for in vivo targeting.

In summary, we demonstrated that GLP-2 treatment decreased hepatic and increased intestinal disposition of a prototypical xenobiotic, CDBN, administered systemically by reducing expression of hepatic GST-Mu and increasing expression of intestinal GST-Alpha and Mrp2, respectively.
