ABSTRACT

Polybrominated diphenyl ethers (PBDEs) are persistent environmental toxicants associated with increased risk for metabolic syndrome. Intermediary metabolism is influenced by the intestinal microbiome. To test the hypothesis that PBDEs reduce host-beneficial intermediary metabolites in an intestinal microbiome-dependent manner, nine-week old male conventional (CV) and germ-free (GF) C57BL/6 mice orally gavaged once daily with vehicle, BDE-47, or BDE-99 (100 µmol/kg) for four-days. Intestinal microbiome (16S rDNA sequencing), liver transcriptome (RNA-Seq), and intermediary metabolites in serum, liver, as well as small and large intestinal contents (SIC and LIC; LC-MS) were examined. Changes in intermediary metabolite abundances in serum, liver, and SIC, were observed under basal conditions (CV versus GF mice) and by PBDE exposure. PBDEs altered the largest number of metabolites in the LIC; most were regulated by PBDEs in GF conditions. Importantly, intestinal microbiome was necessary for PBDE-mediated decreases in branched chain and aromatic amino acid metabolites including 3-indolepropionic acid, a tryptophan metabolite recently shown to be protective against inflammation and diabetes. Gene-metabolite networks revealed a positive association between the hepatic glycan synthesis gene alpha-1,6-mannosyltransferase (Alg12) mRNA and mannose which are important for protein glycosylation. Glycome changes have been observed in patients with metabolic syndrome. In LIC of CV mice, 23 bacterial taxa were regulated by PBDEs. Correlations of certain taxa with distinct serum metabolites

DMD # 86538

further highlight a modulatory role of the microbiome in mediating PBDE effects. In summary, PBDEs impact intermediary metabolism in an intestinal microbiome-dependent manner, suggesting that dysbiosis may contribute to PBDE-mediated toxicities including metabolic syndrome.

INTRODUCTION

Polybrominated diphenyl ethers (PBDEs) have been added to a myriad of consumer products as flame retardants (EU, 2001). While there are 209 predicted PBDE congeners stemming from the degree of bromination and stereochemistry, three commercial formulations were manufactured and used in the US (ATSDR, 2017). One mixture, known as commercial pentaBDE and sold under several trade names, was primarily applied to furniture cushion foam and carpet pads. OctaBDE and DecaBDE mixtures, also sold under different trade names, were primarily applied to plastic components of computers, televisions and other electronics (ATSDR, 2017).

Despite the fact that commercial formulations are no longer produced in, or imported into the US, PBDEs are ubiquitous in human serum and breast milk samples. Recent data from the Methods Advancement for Milk Analysis (MAMA) Study showed that the median serum concentration of BDE-47 was 18.6 ng/g lipid and 3.9 ng/g lipid for BDE-99 (Marchitti *et al.*, 2017). Median breast milk concentrations for BDE-47 were observed in the same study to be 31.5 ng/g lipid, and 6 ng/g lipid for BDE-99. One route of exposure is from household and work-place dust that is contaminated from PBDE-containing products (Hites, 2004; US-EPA, 2012; ATSDR, 2017). In addition, PBDEs are environmentally persistent and bio-accumulative, facilitating human exposures

DMD # 86538

through diet, especially dairy, fish, and meat (Schecter *et al.*, 2004; Schecter *et al.*, 2010; ATSDR, 2017). Two commercial PBDE formulations (e.g. DE-71 and Bromkal 70-5DE) were analyzed for individual congeners and consisted of 36-42% BDE-47 (tetra-brominated), as well as 42-48% BDE-99 (penta-brominated), thus BDE-47 and BDE-99 account for ~80-90% of total PBDEs in these mixtures. (Sanders *et al.*, 2005; La Guardia *et al.*, 2006). BDE-47 and BDE-99 are also two of the most prevalent PBDE congeners found in human samples (Sjödin *et al.*, 2001; Schecter *et al.*, 2003; Imm *et al.*, 2009; Marchitti *et al.*, 2017).

Furthermore, recent epidemiological and animal studies have associations between PBDEs and signs of diabetes and metabolic syndrome. In two independent case-control studies, serum concentrations of BDE-47 in participants with diabetes were significantly associated with increased risk of diabetes (Zhang *et al.*, 2016). In a study among obese individuals, adipose tissue concentrations of both BDE-47 and BDE-99 were significantly elevated in insulin resistant participants compared to insulin sensitive participants (Helaleh *et al.*, 2018). BDE-47 and BDE-99 concentrations were also associated with adipose tissue concentrations of insulin and interleukin-6. BDE-47 was associated with alkaline phosphatase, which is a biomarker for dysfunction in hepatobiliary secretion and has also been shown to interfere with rodent glucose homeostasis (McIntyre *et al.*, 2015; Zhang *et al.*, 2016). Rats exposed to DE-71, one of the commercial PBDE mixtures primarily made up of BDE-47 and BDE-99 as well as other minor constituents, exhibited changes in liver gene expression

DMD # 86538

patterns that matched patterns associated with metabolic syndrome (Sanders *et al.*, 2005; Dunnick *et al.*, 2012). However, research into mechanisms for PBDE-mediated changes in intermediary metabolism is ongoing .

The dynamic and diverse populations of microbes that populate the lower gastrointestinal tract, collectively known as the intestinal or gut microbiome, are known to interact with host intermediary and xenobiotic metabolism (Nicholson *et al.*, 2012; Li *et al.*, 2017). We have previously shown that the intestinal microbiome modifies PBDE-mediated effects on bile acids as well as the expression of genes involved in xenobiotic biotransformation (Li *et al.*, 2017; Li *et al.*, 2018). However, little is known regarding PBDE-mediated intermediary metabolic changes in rodents and a potential modulatory role for the intestinal microbiome. Thus, in this study we integrated transcriptomics, targeted metabolomics, and microbial 16S rDNA profiling to evaluate the effects of PBDEs on intermediary metabolism and test our hypothesis that PBDEs down-regulate beneficial intermediary metabolites in an intestinal microbiome-dependent manner.

DMD # 86538

MATERIALS AND METHODS

Chemicals: BDE-47 (cat. no.: N-105220-10mg, CAS: 5346-43-1) and BDE-99 (cat. no.: FF-BDE-099N-80MG, CAS: 60348-60-9) were purchased from Chem Service, Inc (West Chester, PA), and Accustandard, Inc. (New Haven, CT), respectively. Phosphate-buffered saline (pH 7.4, cat no.: 10010023) was purchased from Thermo Fisher Scientific (Waltham, MA). De-ionized (DI) water was provided in-house by a Synergy Ultrapure Water System from EMD Millipore (Billerica, MA). The un-labeled metabolite standards were purchased from Sigma-Aldrich (St. Louis, MO) and Fisher Scientific (Pittsburgh, PA) and labeled standards were purchased from Cambridge Isotopes (Tewksbury, MA) (Zhu *et al.*, 2014). Ammonium acetate (cat. no.: A11450, cas no.: 631-61-8; LC-MS grade) and acetic acid (cat. no.: A11350, cas no.: 64-19-7; LC-MS grade) came from Fisher Scientific (Pittsburgh, PA). Acetonitrile (ACN, cat. no.: 1.00029, cas no.: 75-05-8) and methanol (cat. no.: 1.06035, cas no.: 67-56-1) both LC-MS grade), ammonium bicarbonate (cat. no.: 09830, cas no.: 1066-33-7; purity >99.99%), and all other chemicals and reagents, unless indicated otherwise, were purchased from Sigma Aldrich (St. Louis, MO).

Animals: As previously reported (Li *et al.*, 2017; Li *et al.*, 2018) and briefly summarized here, eight-week-old male C57BL/6J CV mice were purchased from the Jackson Laboratory (Bar Harbor, ME). Mice were acclimated at the University of Washington for one week prior to experiments. The initial GF mice, which are

DMD # 86538

on a C57BL/6J background, were purchased from the National Gnotobiotic Rodent Resource Center (University of North Carolina, Chapel Hill, NC). Breeding and colony management of GF mice was performed by the University of Washington Gnotobiotic Animal Core. All mice were housed according to the Association for Assessment and Accreditation of Laboratory Animal Care International guidelines. At nine-weeks of age, the mice ($n = 5$ per group) were exposed to vehicle (corn oil (CO), 10 ml/kg), BDE-47 [48.5mg/kg (100 μ mol/kg)] or BDE-99 [56.5 mg/kg or (100 μ mol/kg)] via oral gavage once daily for four consecutive days. All mice were euthanized using CO₂ narcosis followed by cardiac puncture 24 hr after the final PBDE dose. During the cardiac puncture, blood was collected from the heart with a 25-gauge needle and put into a serum separator tube. Serum was collected and stored at -80 °C after centrifugation for 10 min at 2000 g at 4 °C. Liver tissue was frozen in liquid nitrogen and stored at -80 °C for further analysis. Small (SIC) and large (LIC) intestinal contents were collected as a pellet first by flushing the lumen with 10mM dithiothreitol (DTT) in PBS (Sigma Aldrich, St. Louis, MO) and then centrifuging the luminal contents at 20,000 g for 30 min at 4 °C. All animal studies were approved by the Institutional Animal Care and Use Committee at the University of Washington.

RNA Isolation and sequencing: RNA isolation and sequencing methods were previously reported (Li *et al.*, 2017). Briefly, total RNA was isolated from frozen liver tissue ($n=2-4$ /group) using RNA-Bee (Tel-Test Inc., Friendswood, TX).

DMD # 86538

Construction of cDNA libraries and sequencing was performed as previously reported (Li *et al.*, 2017). Libraries were constructed with an Illumina TruSeq Stranded mRNA kit (Illumina, San Diego, CA) and integrity was quantified using an Agilent 2100 Bioanalyzer. Libraries were sequenced using 50 bp paired end reads on an Illumina HiSeq 2000.

16S rDNA sequencing: The sequencing of the LIC microbial DNA from CV mice (n=3/group) was previously reported (Li *et al.*, 2018). Briefly, DNA from the V4 region of the 16S rRNA gene was amplified and 250 bp paired end sequencing was performed on a HiSeq 2500 sequencer.

Serum preparation for aqueous metabolite measurements: Frozen serum samples were first thawed overnight under 4°C, and 50 µL of each serum sample was placed in a 2 mL Eppendorf vial. The initial step for protein precipitation and metabolite extraction was performed by adding 250 µL MeOH. The mixture was then vortexed for 10s and stored at -20°C for 30 min, followed by centrifugation at 14,000 RPM for 10 min at 4 °C. The supernatants (200 µL) were collected into a new Eppendorf vial, and dried under vacuum using an Eppendorf Vacufuge (Eppendorf, Hauppauge, NY). The dried samples were reconstituted in 600 µL of 40% Solvent A/60% Solvent B (see details in the LC-MS method section).

DMD # 86538

Tissue preparation for aqueous metabolite quantifications: The sample preparation is the same for liver, as well as small and large intestinal contents. Briefly, each tissue sample (~10 mg) was homogenized in 200 µL water in an Eppendorf tube using a Bullet Blender homogenizer (Next Advance, Averill Park, NY). Then 800 µL MeOH was added, and after vortexing for 10 s, the samples were stored on dry ice for 30 min. The samples were then sonicated in an ice bath for 10 min. The samples were centrifuged at 14,000 RPM for 10 min (4 °C), and 800 µL supernatant was transferred to a new Eppendorf tube. The samples were then dried under vacuum using an Eppendorf Vacufuge (Eppendorf, Hauppauge, NY). Prior to MS analysis, the obtained residue was reconstituted in 600 µL of 40% Solvent A/60% Solvent B (see details in the LC-MS method section).

Measurements of aqueous metabolites using LC-MS: A robust targeted LC-MS/MS method has been developed (Zhu *et al.*, 2014) and used in a growing number of studies (Barton *et al.*, 2015; Carroll *et al.*, 2015; Gu *et al.*, 2015; Reyes *et al.*, 2015; Sood *et al.*, 2015; Sperber *et al.*, 2015; Zhu *et al.*, 2015; Deng *et al.*, 2016; Gu *et al.*, 2016). Briefly, the LC-MS/MS experiments were performed on a Waters Acquity I-Class UPLC TQS-micro MS (Waters, Milford, MA) system. Each prepared serum or tissue sample was injected twice, 2 µL and 5 µL for analysis using positive and negative ionization mode, respectively. Chromatographic separation was performed on a Waters Xbridge BEH Amide

DMD # 86538

column (2.5 μ m, 2.1 x 150 mm) at 40 °C. The flow rate was 0.3 mL/min. For positive mode, the mobile phase was composed of solvent A (5 mM ammonium acetate in H₂O with 0.1% formic acid) and solvent B (ACN with 0.1% acetic acid). For negative mode, Solvent A was 10 mM ammonium bicarbonate in H₂O, and Solvent B was ACN. The LC gradient conditions were the same for both positive and negative ionization modes. After an initial 1.5 min isocratic elution of 10% A, the percentage of Solvent A was increased to 65% at t=9 min. Then the percentage of A was kept the same (65%) for 5 min (t=14 min), and the percentage of A was decreased back to 10% at t=15 min to prepare for the next injection. The total experimental time for each injection was 30 min. The metabolite identities were confirmed by spiking mixtures of standard compounds. The extracted peaks were integrated using the TargetLynx software (Waters, Milford, MA). A list of all metabolites on the panel can be found in Supplemental Table 1. Supplemental Tables 2-5 show mean abundance values and standard errors for all metabolites by exposure group that were detectable in each bio-compartment.

Data Analysis

RNA-Seq: Preliminary analyses of the FASTQ files used in this study, which were deposited by our group in NCBI's Gene Expression Omnibus (GEO) (GEO accession number GSE101650) during publication of a previous manuscript, have been previously reported (Li et al., 2017). Abundance was expressed as

DMD # 86538

fragments per kilobase of transcript per million mapped reads (FPKM). Differential expression analysis was performed using Cuffdiff (Trapnell *et al.*, 2010). The differentially expressed genes were defined as false discovery rate (FDR) adjusted *p*-value <0.05, in at least one of the PBDE-exposed groups compared to the vehicle-exposed group of the same enterotype, which in this study refers to CV as opposed to GF mice, as well as genes that were differentially expressed by the lack of intestinal microbiome under basal conditions. Assignment of genes into intermediary metabolism categories was performed using KEGG metabolism pathways in R 3.4.3 (Kanehisa and Goto, 2000; Kanehisa *et al.*, 2016; Kanehisa *et al.*, 2017; R Core Team, 2017). Mean FPKM standard errors and metabolism categories for intermediary metabolism genes for each treatment group can be found in Supplemental Table 6. Fold changes and associated FDR adjusted *p*-values for comparisons between PBDE treated mice and enterotype-matched vehicle controls and between CV and GF mice under basal conditions can be found in Supplemental Table 7. Heatmaps were also built in R 3.4.3 (base, gplots package) (Warnes *et al.*, 2013; R Core Team, 2017). Because many gene products have multiple functions, many of the differentially expressed genes classified as intermediary metabolism genes here were reported as drug processing genes previously, mainly cytochrome P450s (Cyps) by Li *et al* (Li *et al.*, 2017).

DMD # 86538

Aqueous Metabolites: Relative abundance values for each metabolite in each bio-compartment were compared using two-way ANOVA followed by Tukey's post-hoc test using R 3.4.3 (base, lsmeans and multcomp packages) (Hothorn *et al.*, 2008; Lenth, 2016; R Core Team, 2017). Heatmaps were also built in R (base, gplots package) (Warnes *et al.*, 2013; R Core Team, 2017). Gene-Metabolite network analyses were performed using MetaboAnalyst (Chong *et al.*, 2018) (<http://www.metaboanalyst.ca>) using all differentially regulated intermediary metabolism genes with a fold-change > 2 (implemented to emphasize most highly changed genes) and significantly altered metabolites in the liver. Pearson's correlations for gene and metabolite network members were calculated using R 3.4.3 (base, corrplot, and Hmisc packages) (Harrell *et al.*, 2016; Wei and Simko, 2016; R Core Team, 2017). Significant gene-metabolite pair correlation plots and bar plots were created using R3.4.3 (base, ggplot2 package) (Wickham, 2009; R Core Team, 2017).

16S rDNA sequencing: The 16S rDNA sequencing data were analyzed using QIIME v1.9.1 as previously reported (Li *et al.*, 2018). Relative abundance was expressed as percentage of operational taxonomical units (% OTUs) and was examined for PBDE treatment effects using a one-way ANOVA followed by Tukey's HSD post-hoc test in R 3.4.3 ($p < 0.05$) (R Core Team, 2017). In this study, these data were used for investigating potential associations between individual microbial taxa and serum aqueous metabolites. Spearman's

DMD # 86538

correlations for differentially regulated microbial OTUs and serum metabolites by PBDEs were performed using R (base, corrplot package) (Wei and Simko, 2016; R Core Team, 2017). Significant gene-metabolite pair correlation plots and bar plots were created using R (base, ggplot2 package) (Wickham, 2009).

Glutathione: Levels of total glutathione in liver were quantified using a fluorescence-based microplate assay, as previously described (White *et al.*, 2003; McConnachie *et al.*, 2007; Weldy *et al.*, 2011; Scoville *et al.*, 2019)

RT-qPCR: Expression of Alg12, Gclc, and Nqo1 were measured using RT-qPCR. Total RNA was reverse transcribed to cDNA using the High Capacity cDNA Reverse Transcription Kit (Applied Biosystems, Foster City, CA). The cDNAs were then amplified using Power SYBR™ Green PCR Master Mix (Applied Biosystems, Foster City, CA) using a BioRad CFX384 Real-TimePCR Detection System (Bio-Rad, Hercules, CA). Primers were made by Integrated DNA Technologies (Coralville, IA) and primer sequences can be found in Supplemental Table 8.

DMD # 86538

RESULTS

Effects of PBDEs on aqueous metabolites in serum of CV and GF mice

In order to determine the impact of PBDE exposure on the dynamic systems of intermediary metabolism, aqueous metabolites from several bio-compartments were quantified using LC-MS. Of the total 215 aqueous metabolites on the panel a total of 139 were detectable in serum (Supplemental Table 2). As shown in Figure 1, the relative abundances of 13 metabolites in serum were decreased and 2 increased by lack of intestinal microbiome, PBDE exposure, or both, compared to CV control mice.

Six metabolites were decreased in the serum of GF mice under basal conditions including the tryptophan metabolites 3-indoxylsulfate, 3-indolepropionic acid (3-IPA), the phenylalanine metabolites phenylpyruvic acid and 3-phenyllactic acid, the branched short chain fatty acid (BSCFA) isobutyric acid, and the fatty acid amide *N*-acetylethanolamine. Acetylglycine and the saturated long-chain fatty acid palmitic acid were increased in serum under basal conditions in GF mice.

PBDEs differentially regulated 12 serum metabolites. Interestingly, the relative abundances of 3 tryptophan metabolites, namely the microbial metabolites 3-IPA and indole-3-acetic acid, as well as the host metabolite kynurenone, were all decreased by both PBDE congeners, in CV but not GF mice. PBDEs also decreased *N*-acetylethanolamine and phenyllactic acid in CV

DMD # 86538

but not GF mice. BDE-47 decreased the relative abundances of the amino acid valine and its non-proteogenic isomer norvaline whereas BDE-99 increased phenylpyruvic acid, isobutyric acid, and the carbohydrate metabolite sorbitol, also in CV but not GF mice. In contrast, the lack of gut microbiota predisposed GF mice to PBDE-mediated decreases in the relative abundance of metabolites derived from the branched chain amino acid (BCAA) valine. BDE-47 increased alpha-ketoisovaleric whereas both BDE-47 and BDE-99 mediated increased alpha-hydroxyisovaleric acid.

Effects of PBDEs on aqueous metabolites in liver of CV and GF mice

In liver, 156 aqueous metabolites were detectable (Supplemental Table 3). As shown in Figure 2, under basal conditions, 11 out of the 16 metabolite changes occurred between CV and GF mice. The relative abundances of the sialic acid *N*-acetylneuraminic acid, the purine metabolite urate, and the amino acid glycine were all increased in GF mice. The relative abundances of isobutyric acid, 3-phenyllactic acid, the amino acid derivative carnitine, the amino acid derivative ketoleucine, the carbohydrate metabolite glucuronic acid, and diet-derived metabolites (benzoic acid, phthalic acid, 4-methoxyphenylacetic acid) were all decreased in GF mice.

In CV mice, BDE-47 had minimal effect on the hepatic aqueous metabolite profiles. However, BDE-99 decreased relative abundances of carnitine, the carbohydrate mannose, the antioxidant glutathione, the homocysteine metabolite

DMD # 86538

cystathionine, and the vitamin nicotinamide, all in CV but not GF mice. The lack of gut microbiota predisposed GF mice to BDE-47-mediated decreases in the glutamine derivative acetyl-L-glutamine.

Effects of PBDEs on aqueous metabolites in SIC of CV and GF mice

A total of 147 aqueous metabolites were detectable in the SIC (Supplemental Table 4). As shown in Figure 3, there were 15 metabolites that were decreased in SIC of GF mice under basal conditions, including several amino acids (phenylalanine, tryptophan, arginine, and cysteine, citrulline, asparagine), amino acid derivatives (carnitine, acetyl-L-glutamine, creatine, acetylornithine, and 4-imidazoleacetic acid); the carbohydrate metabolite sorbitol, as well as other organic compounds (folinic acid, and 4-aminophenol). Conversely, the relative abundance of dextrose (also known as D-glucose) was increased in the SIC of GF mice under basal conditions.

PBDE exposure differentially regulated six metabolites in the SIC of CV mice but not GF mice. Asparagine, creatine, sorbitol, and cysteine were decreased by both PBDE congeners, folinic acid was decreased by BDE-47, and acetyl-L-glutamine was decreased by BDE-99. In contrast, the lack of gut microbiota predisposed GF mice to BDE-47 mediated increases in the relative abundances of amino acid derivatives (3-phenyllactic acid, acetyl-L-tyrosine), the redox active coenzyme NAD, and the glycerol derivative glyceric acid; BDE-99

DMD # 86538

mediated increase in carnitine; and BDE-99 mediated decrease in 4-hydroxybenzoic acid.

Effects of PBDEs on aqueous metabolites in LIC of CV and GF mice

A total of 147 aqueous metabolites were detectable in the SIC (Supplemental Table 5). As shown in Figure 4, PBDEs differentially regulated 26 metabolites in the LIC—the highest among the four bio-compartments examined. Interestingly, the relative abundances for the majority of metabolites (24 out of 26) in the LIC were changed by PBDEs only in GF conditions but not in CV conditions. The two exceptions are the tryptophan metabolite indole-3-pyruvic acid, which was reduced in the LIC of CV mice by BDE-47 (the basal relative abundance in GF mice was also lower), and folinic acid, which was increased by BDE-99 in CV but not GF mice.

The lack of gut microbiome predisposed GF mice to PBDE-mediated increases in 17 LIC metabolites. As compared to vehicle-exposed GF mice, both BDE-47 and BDE-99 increased the relative abundances of the amino acids leucine and methionine, amino acid derivatives (4-hydroxyproline, 5-aminoleulic acid, and acetylcarnitine), the choline metabolism intermediate and methionine precursor betaine, and the coenzyme A precursor pantothenic acid. BDE-47 increased relative abundances of the nucleic acid 2-deoxycytidine and amino cysteine in LIC of GF mice, whereas BDE-99 increased several amino acids (norleucine, isoleucine, L-alloisoleucine, tyrosine, phenylalanine, and

DMD # 86538

tryptophan), the tryptophan metabolite indole-3-lactic acid and the carbohydrate metabolite glycerol-3-phosphate.

The lack of gut microbiota also predisposed GF mice to PBDE-mediated decreases in seven metabolites. Both BDE-47 and BDE-99 decreased the relative abundances of carbohydrate metabolites sorbitol and raffinose in the LIC of GF mice as compared to control GF mice. In addition, BDE-47 decreased relative abundances of the nucleic acid adenine and carbohydrate metabolite pyruvate, whereas BDE-99 decreased the NAD precursor nicotinic acid, the histamine metabolite 4-imidazoleacetic acid, and the fatty acid amide *N*-acetylethanolamine in the LIC of GF mice.

Differentially abundant metabolites unique and common to different bio-compartments are summarized in Supplemental Figure 4. Treatment group specific and common differentially abundant metabolites within each bio-compartment are summarized in Supplemental Figure 5.

Liver intermediary metabolism gene expression and gene-metabolite networks

As shown in Figures 5 and 6, 133 intermediary metabolism related genes belonging to one or more of the KEGG pathways (carbohydrate, glycan, amino acid, vitamin and co-factor, nucleotide, and energy metabolism) were differentially expressed due to either PBDE exposure, lack of gut microbiota, or both in liver. Specifically, carbohydrate metabolism and glycan biosynthesis and

DMD # 86538

metabolism were represented by 38 and 13 differentially expressed genes, respectively (Figure 5A). Amino acid metabolism was represented by 70 differentially expressed genes (Figure 6A) and vitamin and co-factor metabolism contained 44 genes (Figure 6C). Nucleotide metabolism and energy metabolism contained 11 and 10 differentially expressed genes, respectively (Supplemental Figure 1). Metabolism category labels for genes in Figure 5A, Figure 6A, Figure 6C, and Supplemental 1 can be found in Supplemental Table 6.

To integrate the liver intermediary metabolism transcriptomic and metabolomic data and identify potential gene-metabolite regulatory networks impacted by PBDEs, network analysis was performed using Metaboanalyst, with all differentially regulated intermediary metabolism related genes and aqueous metabolites in liver. As Metaboanalyst was built for human genes, Ensembl Biomart was used to retrieve human homologs.

The Network Explorer module revealed three networks using the list of differentially regulated liver genes and metabolites. One of the networks generated by Metaboanalyst centered on the carbohydrate metabolite mannose with connections (representing interactions from literature found by Network Explorer) to the carbohydrate metabolism gene glucokinase (GCK), the glycan synthesis gene alpha-1,6-mannosyltransferase (ALG12), and the carbohydrate mannose (Figure 5B). In addition, a significant correlation was observed in our data between ALG12 expression and the relative abundance of mannose (Figures 5C), and BDE-99 decreased both in CV but not GF mice (Figure 5D).

DMD # 86538

Expression of Alg12 measured using RT-qPCR matched RNA-seq expression patterns across treatment groups (Supplemental Figure 2).

The second gene-metabolite network that was generated by Metaboanalyst centered around glutathione (Figure 6B), which is synthesized from three amino acids (glycine, glutamate, and cysteine). Glutathione was connected to the amino acid metabolism genes dopa decarboxylase (DDC), cytochrome P450 1A2 (CYP1A2 representing the mouse Cyp1a2), CYP3A5 (representing several mouse Cyp3a isomers), and glutamate-cysteine ligase catalytic subunit (GCLC representing the mouse Gclc), which is a glutathione synthesis gene utilizing glutamate and cysteine as substrates (Figure 6B). Expression of Cyp1a2 and Cyp3a11, which was the most highly expressed Cyp3a isoform, have been validated using RT-qPCR as previously reported (Li *et al.*, 2017). NAD(P)H dehydrogenase, quinone 1 (NQO1), which is classified as a vitamin and cofactor metabolism gene as well as a prototypical target gene of the anti-oxidative stress sensor nuclear factor erythroid 2 like 2 (Nrf2), is also connected to glutathione (Figures 6B and 6C) (Ross and Siegel, 2018). Levels of liver glutathione were also measured independently using a fluorescence-based microplate assay. Interestingly, the pattern across exposure groups was similar to that found using the LC-MS based aqueous metabolite panel, suggesting that although the transcriptomic changes in glutathione synthesis/metabolism related genes occur following PBDE exposure and the absence of gut microbiome, the liver serves as an efficient repertoire to buffer the oxidative stress by maintaining

DMD # 86538

the total glutathione levels (Supplemental Figures 3A and 3B). To validate the RNA-Seq results, RT-qPCR was performed for the mRNA expression of Gclc and Nqo1, and the expression patterns were consistent among the two assays across exposure groups (Supplemental Figures 3C, 3D, 3E and 3F).

The third network that was generated by was centered on the vitamin nicotinamide, which was connected to vitamin and cofactor processing genes CYP2D6 and CYP3A5, which are represented by several mouse Cyp2d and Cyp3a isoforms, respectively (Figure 6D).

Correlations between serum metabolites and gut microbiota

To investigate the intersection of PBDE regulation of serum metabolites and the gut microbiome at the individual taxa level, the relative abundances of 23 gut microbial taxa that were changed by PBDEs were tested for correlation with PBDE-regulated serum metabolites. Serum metabolites were prioritized because the changes in this bio-compartment could have systemic effects. Of the 23 taxa, 19 were significantly correlated with at least one serum aqueous metabolite (Figure 8).

Regarding amino acid metabolism, the microbial tryptophan metabolite 3-IPA was positively correlated with the largest number of taxa (8), all of which belong to the phylum Firmicutes, and apart from one taxon from the Clostridia class, all belong to the class Bacilli (Figure 8). Four of the Bacilli belong to the Bacillales order and three are Lactobacillales. Within the Bacillales order, two

DMD # 86538

taxa were in the *Staphylococcaceae* family, one is a *Baciliaceae*, and the other is unresolved at the family level and beyond. Both *Staphylococcaceae* are *Staphylococcus* at the genus level, but neither is resolved at the species level. The taxon from the *Baciliaceae* family is *Bacillus* at the genus level and also unresolved at the species level. Within the Lactobacillale order, two are in the *Lactobacillaceae* family, and the other taxon is unresolved at the family level and beyond. Both *Lactobacillaceae* are *Lactobacillus* at the genus level. One is the *reuteri* species and the other is unresolved at the species level. The taxon in the Clostridia class is Clostridiales (order), *Lachnospiraceae* (family), and unresolved at the genus and species levels.

Another microbial tryptophan metabolite, namely indole-3-acetic acid, is positively correlated with 2 microbial taxa and inversely correlated with one (Figure 8). The first positively correlated taxon is Firmicutes (phylum), Clostridia (class), Clostridiales (order), *Lachnospiraceae* (family), *Butyrivibrio* (genus), and unresolved at the species level. The second positively correlated taxon is Firmicutes (phylum), Erysipelotrichi (class), Erysipelotrichales (order), *Erysipelotrichaceae* (family), and unresolved at the genus and species level. The inversely correlated taxon has the same taxonomy as the *Erysipelotrichaceae* (family), belongs to the *Allobaculum* genus, and is unresolved at the species level.

The phenylalanine metabolite phenyllactic acid is positively correlated with seven gut microbial taxa (Figure 7). Two of the seven taxa are the same

DMD # 86538

Staphylococcus genus as described above. An additional two are the same *Lactobacillus* genus taxa, one identified as *reuteri*, and the other unresolved at the species level. The fifth taxon associated with phenyllactic acid is Bacillales at the order level and is also previously described above. One of the remaining taxa associated with phenyllactic acid is Actinobacteria (phylum), Coriobacteriia (class), Coriobacteriales (order), *Coriobacteriaceae* (family), *Adlercreutzia* (genus), and unresolved at the species level. The other taxon is Firmicutes (phylum), Clostridia (class), Clostridiales (order), *Mogibacteriaceae* (family), and unresolved at the genus and species levels.

BCAAs valine and norvaline, are positively correlated with the same taxon from the *Butyrivibrio* genus as indole-3-acetic acid (Figure 7). They are both also inversely correlated with the same taxon from the *Allobaculum* genus as indole-3-acetic acid (Figure 7).

The fatty acid amide *N*-acetylethanolamine is positively correlated with 4 microbial taxa (Figure 7). The full taxonomy of three have already been described; *Adlercreutzia* (genus), *Lactobacillus* (genus – unresolved at species level), and *Mogibacteriaceae* (family). The 4th taxa associated with *N*-acetylethanolamine has the same taxonomy as the *Lactobacillus* (genus), and also unresolved at the species level, but is distinct from the *Lactobacillus* (genus) associated with 3-IPA and 3-phenyllactic acid.

Three metabolites, namely the branched short chain fatty acid isobutyric acid, the phenylalanine metabolite and phenyllactic acid precursor phenylpyruvic

DMD # 86538

acid, and the carbohydrate sorbitol, are all positively correlated with a microbial taxon that is Firmicutes (phylum), Clostridia (class), Clostridiales (order), *Lachnospiraceae* (family), *Dorea* (genus), and unresolved at the species level (Figure 7). These same three metabolites are also inversely associated with *Akkermansia* (genus) *mucinophila* (species), which belongs to Verrucomicrobia phylum, Verrucomicrobiae class, Verrucomicrobiales (order), and *Verrucomicrobiaceae* family.

DMD # 86538

DISCUSSION

Although the commercial pentaBDE (comprised mainly of BDE-47 and BDE-99) and octaBDE formulations of PBDEs were voluntarily taken off the market in 2004 and decaBDE by 2014 (ATSDR, 2017), PBDEs are still readily detectable in human samples. While concentrations of pentaBDE constituents have previously been observed to decline since their withdrawal, the trend may have flattened out and concentrations may now be on the rise (Ma *et al.*, 2013; Zota *et al.*, 2013; Hurley *et al.*, 2017; Parry *et al.*, 2018; Cowell *et al.*, 2019). This is likely due to the persistent and bio-accumulative nature of PBDEs, the recycling of PBDE-containing products worldwide, and the potential for higher brominated PBDES to degrade in the environment into lower brominated forms (Bezares-Cruz *et al.*, 2004; Zeng *et al.*, 2008).

As originally reported in Li *et al.*, 2017, male mice were dosed once daily for four consecutive days with 48.5mg/kg BDE-47 and 56.5 mg/kg BDE-99 (100 μ mol/kg). While these doses are high compared to estimated human PBDE exposures, they were selected to allow for comparison of acute xenobiotic metabolism gene expression changes with previously published studies (Pacyniak *et al.*, 2007; Sueyoshi *et al.*, 2014; Li *et al.*, 2017). In this study, metabolomic data from archived samples collected by Li *et al.* was integrated with previously reported liver gene expression (Li *et al.*, 2017) and intestinal microbiome data (Li *et al.*, 2018) to explore acute PBDE effects on intermediary metabolism.

DMD # 86538

Limitations of this study include sample size, the evaluation of only male mice, and that is mainly associative, all of which stem from the use of archived samples and previously reported datasets. As reported in Li *et al.*, 2017, male mice were used exclusively due to changes in hormone levels due to the estrous cycle. Such hormonal variation is also relevant to this study as it could independently impact glucose metabolism and other intermediary metabolic pathways (Mauvais-Jarvis *et al.*, 2013). Sample size for the three data sets used in this study was also a limitation. However, even with relatively small sample sizes, we were able to identify statistically significant PBDE and gut-microbiome associated changes in intermediary metabolites, expression of associated genes, and correlations among metabolites and several previously reported human health and disease relevant microbes (Li *et al.*, 2018). Importantly, future mechanistic studies will be needed to fully validate the observed findings of this study.

Tryptophan pathway and involvement of PBDEs in metabolic syndrome

Notably, serum 3-IPA, which is a tryptophan microbial metabolite known to be protective against diabetes and inflammation, was decreased by both PBDE congeners in CV mice but not in GF mice (Figure 1). This highlights the potential involvement of the tryptophan metabolism pathway in PBDE-mediated metabolic disorders because 3-IPA is produced by intestinal bacteria and accumulates in the blood to modulate systemic effects (Dodd *et al.*, 2017) such as metabolic

DMD # 86538

syndrome. Specifically, 3-IPA is associated with reduced risk of type-II diabetes in epidemiology studies and is suggested to preserve pancreatic beta cell function (de Mello *et al.*, 2017). These observations in humans were further supported in rats because 3-IPA improved glucose metabolism evidenced by reduced fasting plasma insulin and the homeostatic model assessment index of insulin resistance (Abildgaard *et al.*, 2018). In humans, BDE-47 was associated with diabetes in two independent community-based epidemiological studies (Zhang *et al.*, 2016), and total PBDEs were linked to increased risk of diabetes during pregnancy (Eslami *et al.*, 2016; Smarr *et al.*, 2016). PBDE-exposed rats developed hyperglycemia and aberrant expression of genes involved in glucose homeostasis (Zhang *et al.*, 2016; Krumm *et al.*, 2018), corresponding to disturbed glucose and insulin metabolism in adipose tissue, disturbed lipid metabolism in liver, and increased ketone concentrations in blood (Cowens *et al.*, 2015). PBDEs disturbed glucose signaling in hepatocytes (Søfteland *et al.*, 2011). *In vitro* studies showed that PBDEs disrupted insulin-producing pancreatic beta cells (Karandrea *et al.*, 2017). Therefore, PBDE-mediated decrease in 3-IPA may be part of the toxification mechanisms for the pathogenesis of diabetes by disrupting glucose and insulin signaling.

Another potential involvement of 3-IPA in metabolic syndrome is inflammation—an important contributor to diabetes (Donath and Shoelson, 2011; Goldfine *et al.*, 2011)—and 3-IPA is known to suppress inflammatory genes by antagonizing aryl hydrocarbon receptor functions (Yisireyili *et al.*, 2017). In

DMD # 86538

addition, 3-IPA is a pregnane X receptor (PXR) ligand in intestine and activation of PXR reduces intestinal inflammation (Cheng *et al.*, 2012; Venkatesh *et al.*, 2014). Conversely, PBDEs have been shown to affect the immune system during development (Zhou *et al.*, 2006; Martin *et al.*, 2009; Bondy *et al.*, 2011; Liu *et al.*, 2012; Koike *et al.*, 2014; Lv *et al.*, 2015), as well as promote inflammation and oxidative stress (Zhang *et al.*, 2013), which are key contributors for the pathogenesis of diabetes (Farah *et al.*, 2008; Vikram *et al.*, 2014; Dominguet *et al.*, 2016; Hojs *et al.*, 2016). Therefore, PBDE-mediated decrease in IPA may also contribute to the pathogenesis of diabetes by promoting inflammation.

Branched chain amino acid metabolites, PBDEs, and adipose tissue metabolism

Isobutyric acid is a branched short-chain fatty acid (BSCFA) derived from the BCAA valine and can be produced by gut bacteria or by host (Liebich and Först, 1984; Zarling and Ruchim, 1987; Cole, 2015). Shown to potentially benefit adipocyte metabolism, isobutyric acid was decreased in this study in GF mice under basal conditions and by BDE-99 in CV mice (Heimann *et al.*, 2016). While there is controversy as to a potentially beneficial or detrimental role for BCAs in obesity and type 2 diabetes, preliminary evidence suggests a potential protective role for their metabolites (Lynch and Adams, 2014; Heimann *et al.*, 2016).

In obesity, adipocytes exhibit inter-related changes including increased basal rates of lipolysis and insulin resistance, which are thought to contribute to

DMD # 86538

systemic insulin resistance (Girousse *et al.*, 2013; Arner and Langin, 2014; Morigny *et al.*, 2016). Treatment of rat adipocytes with isobutyric acid reduced lipolysis and improved basal and insulin-induced glucose uptake (Heimann *et al.*, 2016). Non-branched short chain fatty acids (SCFAs) have also been observed to have similar effects on rat adipocytes (Heimann *et al.*, 2015). In contrast, PBDEs have been associated with increased rat adipocyte lipolysis and decreased glucose oxidation (marker of uptake and metabolism) (Hoppe and Carey, 2012). Furthermore, PBDEs have been associated with insulin resistance among obese humans (Helaleh *et al.*, 2018).

The decreases of the potentially beneficial valine metabolite isobutyric acid and, among GF mice, its upstream metabolic intermediates alpha-ketoisovaleric and alpha-hydroxyisovaleric acid, suggests that PBDEs may promote metabolic syndrome in part by interference with valine/BCAA metabolism.

PBDEs, protein glycosylation, and metabolic syndrome

Liver intermediary metabolism gene expression and aqueous metabolite data were integrated using the Network Explorer module in Metaboanalyst (Chong *et al.*, 2018). One of the resulting networks, consisting of the genes ALG12, GCK, and the carbohydrate mannose, stood out due to a correlation found in the study data between ALG12 and mannose. As part of the N-glycosylation pathway, ALG12 is responsible for the addition of the 8th mannose

DMD # 86538

residue to a growing oligosaccharide that ultimately possess 9 mannoses and 3 glucoses, all of which are added in the endoplasmic reticulum (ER) lumen (Burda and Aebi, 1999; Thiel et al., 2002; Aebi, 2013). As an *N*-glycan, this molecule is subsequently attached to the nitrogen of the side chain of asparagine in a protein by oligosaccharyltransferase (Burda and Aebi, 1999; Aebi, 2013). *N*-glycans on proteins participate in the luminal endoplasmic reticulum associated degradation pathway (ERAD-L) that detects and degrades misfolded proteins (Quan et al., 2008).

Epidemiological studies have found that patients diagnosed with metabolic syndrome have an altered *N*-glycan profile with some components, including those with 7 and 8 mannose residues, being positively associated with signs of metabolic syndrome and some inversely (Lu et al., 2011; McLachlan et al., 2016). In this study, BDE-99 reduced Alg12 expression and the relative abundance of mannose in CV but not GF mice, suggesting that a PBDE microbial metabolite could also contribute to these changes. To our knowledge, the potential for PBDEs and/or PBDE host/microbial metabolites to interfere with protein glycosylation has not been explored. However, future glycomics studies will be necessary to evaluate this potential novel mechanism of PBDE toxicity.

Microbiota correlations with serum metabolites

The present study showed that PBDE mediated decreases in *Lactobacillus reuteri* correlate with serum decreases in the tryptophan metabolite

DMD # 86538

3-IPA. Even though *L. reuteri* is not known to produce 3-IPA, it does produce indole-3-lactic acid, which is a 3-IPA precursor (Dodd *et al.*, 2017). PBDEs also reduced serum indole-3-acetic acid, which is another tryptophan metabolite produced by *L. reuteri* (Cervantes-Barragan *et al.*, 2017). Interestingly, in mouse models where *L. reuteri* is introduced in combination with tryptophan supplementation, indole-3-acetic and indole-3-lactic acid have been shown to promote the development of intestinal T-cells that help immune tolerance to antigens in the diet (Cervantes-Barragan *et al.*, 2017). However, given the small sample size, microbe-metabolite associations should be viewed as preliminary until follow-up studies with larger numbers are completed.

Summary

Taken together, the present study demonstrates that oral PBDE exposure profoundly altered many important intermediary metabolites involved in amino acid, carbohydrate, and lipid metabolism, in a bio-compartment specific manner. While liver metabolites were more influenced by enterotype than PBDEs, metabolites from large intestinal contents were more influenced by PBDEs than by enterotype and such influence occurred almost exclusively in GF conditions. Metabolites from serum and SIC were regulated by both enterotype and PBDEs. Two interesting regulatory patterns were discovered: 1) the presence of gut microbiota is necessary for PBDE-mediated decreases in metabolites, such as those from the tryptophan pathway in serum and those from the metabolism of

DMD # 86538

amino acids and carbohydrates in the SIC; 2) lack of gut microbiota predisposed mice to PBDE-mediated changes metabolites including the majority of those from amino acid and carbohydrate metabolism in the LIC. Correlation analyses among targeted metabolomics, hepatic RNA-Seq, and intestinal 16S rDNA sequencing further established potential mechanisms for PBDE-mediated regulation of intermediary metabolites. Together our observations highlight the potential involvement of dys-regulation of intermediary metabolism as part of the mechanisms underlying the multi-organ toxicities of PBDEs and unveils the important role of gut microbiota as a key internal modifier for PBDE-mediated host response. Future follow-up studies will include mechanistic investigation using male and female wild-type and nuclear receptor knockout mice to assess the impact of key metabolites, identified in this study on PBDE toxicity, dysbiosis, and potential interactions with nuclear receptors. Inflammation, glucose homeostasis, and the effects of high fat diet will also be explored.

FIGURE LEGENDS

Figure 1. Two-way hierarchical clustering dendrogram of aqueous metabolites measured using LC-MS that were differentially regulated across treatment groups in serum of GF and CV mice following exposures to BDE-47 and BDE-99. Euclidian distance and complete linkage were used to generate the dendrogram. Red indicates higher standardized mean metabolite relative abundances (z-scores) and blue lower. Asterisks (*) represent statistically significant differences between corn oil-treated and PBDE treated groups within enterotype (adjusted p-value <0.05, Tukey's HSD post-hoc test). Caret signs (^) represent statistically significant baseline differences between CV and GF mice. Percent change from CVCO are shown for treatment groups with significant changes.

Figure 2. Two-way hierarchical clustering dendrogram of aqueous metabolites measured using LC-MS that were differentially regulated across treatment groups in liver of GF and CV mice following exposures to BDE-47 and BDE-99. Euclidian distance and complete linkage were used to generate the dendrogram. Red indicates higher standardized treatment group mean metabolite relative abundances (z-scores) and blue lower. Asterisks (*) represent statistically significant differences between corn oil-treated and PBDE treated groups within enterotype (adjusted p-value <0.05, Tukey's HSD post-hoc test). Caret signs (^) represent statistically significant baseline differences between CV and GF mice.

DMD # 86538

Percent change from CVCO are shown for treatment groups with significant changes.

Figure 3. Two-way hierarchical clustering dendrogram of aqueous metabolites measured using LC-MS that were differentially regulated across treatment groups in SIC of GF and CV mice following exposures to BDE-47 and BDE-99. Euclidian distance and complete linkage were used to generate the dendrogram. Red indicates higher standardized treatment group mean metabolite relative abundances (z-scores) and blue lower. Asterisks (*) represent statistically significant differences between corn oil-treated and PBDE treated groups within enterotype (adjusted p-value <0.05, Tukey's HSD post-hoc test). Caret signs (^) represent statistically significant baseline differences between CV and GF mice. Percent change from CVCO are shown for treatment groups with significant changes.

Figure 4. Two-way hierarchical clustering dendrogram of aqueous metabolites measured using LC-MS that were differentially regulated across treatment groups in LIC of GF and CV mice following exposures to BDE-47 and BDE-99. Euclidian distance and complete linkage were used to generate the dendrogram. Red indicates higher standardized treatment group mean metabolite relative abundances (z-scores) and blue lower. Asterisks (*) represent statistically significant differences between corn oil-treated and PBDE treated groups within

DMD # 86538

enterotype (adjusted p-value <0.05, Tukey's HSD post-hoc test). Caret signs (^) represent statistically significant baseline differences between CV and GF mice. Percent change from CVCO are shown for treatment groups with significant changes.

Figure 5. Two-way hierarchical clustering dendrogram of carbohydrate and glycan metabolism genes that were differentially regulated across treatment groups in liver of GF and CV mice following exposures to BDE-47 and BDE-99 (A). Gene expression was quantified using RNA-Seq as previously reported (Li *et al.*, 2017) and can be accessed through NCBI GEO (GSE101650). Euclidian distance and complete linkage were used to generate the dendrogram. Red indicates higher standardized mean metabolite relative abundances and blue lower. Asterisks (*) represent statistically significant differences between corn oil-treated and PBDE treated groups (FDR adjusted p-value <0.05). Caret signs (^) represent statistically significant baseline differences between CV and GF mice. Network of differentially regulated carbohydrate (GCK) and glycan (ALG12) metabolism genes (circles) and the significantly altered carbohydrate metabolite Mannose (square), which was quantified using LC-MS, in liver (B). Mouse orthologs for human genes are listed in mixed case. Pearson correlation of log2 abundances of Mannose and Alg2 across treatment group means (C). Means and standard errors of Alg12 and Mannose for each treatment group (D). Asterisks (*) represent statistically significant differences between corn oil-treated

DMD # 86538

and PBDE treated groups (FDR adjusted p-value <0.05, Cuffdiff). Caret signs (^) represent statistically significant baseline differences between CV and GF mice.

Figure 6. Two-way hierarchical clustering dendrogram of amino acid metabolism genes that were differentially regulated across treatment groups in liver of GF and CV mice following exposures to BDE-47 and BDE-99 (A). Gene expression was quantified using RNA-Seq as previously reported (Li *et al.*, 2017) and can be accessed through NCBI GEO (GSE101650). Euclidian distance and complete linkage were used to generate the dendrogram. Red indicates higher standardized mean metabolite relative abundances and blue lower. Network of differentially regulated amino acid metabolism genes (DDC, NQO1, GNMT, CYP1A2, and CYP3A5) (circles) and significantly altered aqueous metabolites (Glycine and Glutathione) (squares), which were measured using LC-MS, in liver (B). Mouse orthologs for human genes are listed in mixed case. Two-way hierarchical clustering dendrogram of vitamin and co-factor metabolism genes that were significantly altered across treatment groups in liver of GF and CV mice following exposures to BDE-47 and BDE-99 (C). Gene expression was measured using RNA-Seq as previously reported (Li *et al.*, 2017) and can be accessed through NCBI GEO (GSE101650). Euclidian distance and complete linkage were used to generate the dendrogram. Red indicates higher standardized mean metabolite relative abundances and blue lower. Network of differentially regulated vitamin metabolism genes (CYP2D6 and CYP3A4) (circles) and the

DMD # 86538

significantly altered aqueous metabolite Nicotinamide (square), which was measured using LC-MS, in liver (square) (D). Asterisks (*) represent statistically significant differences between corn oil-treated and PBDE treated groups (FDR adjusted p-value <0.05). Caret signs (^) represent statistically significant baseline differences between CV and GF mice.

Figure 7. Pearson correlation matrix of differentially regulated gut microbiome OTUs (identified and quantified using 16S rRNA sequencing) and serum metabolites (quantified using LC-MS). Red indicates stronger positive correlations and blue stronger negative.

Supplemental Material

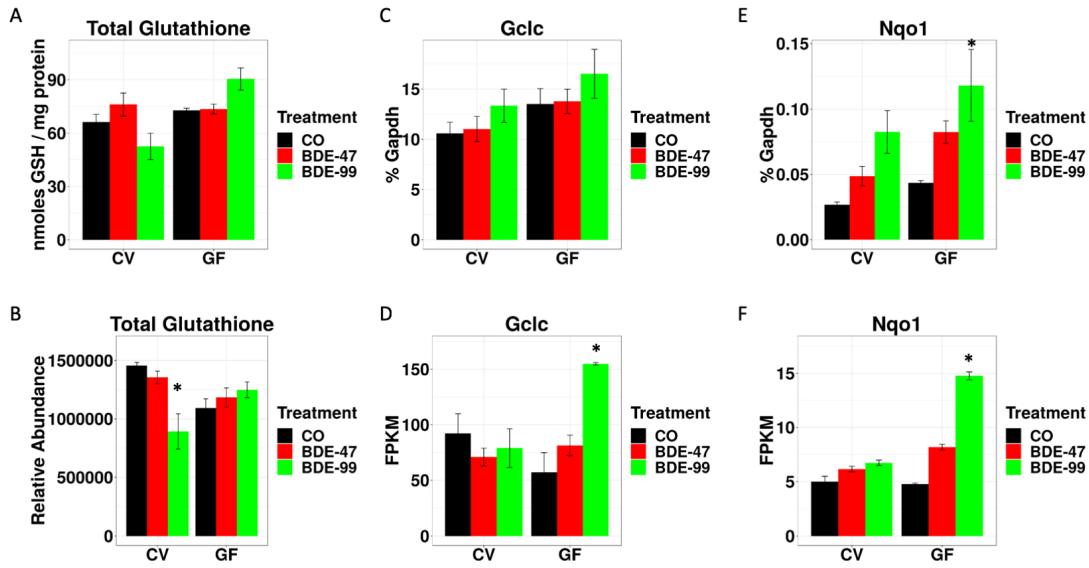

A – Nucleotide Metabolism B – Energy Metabolism

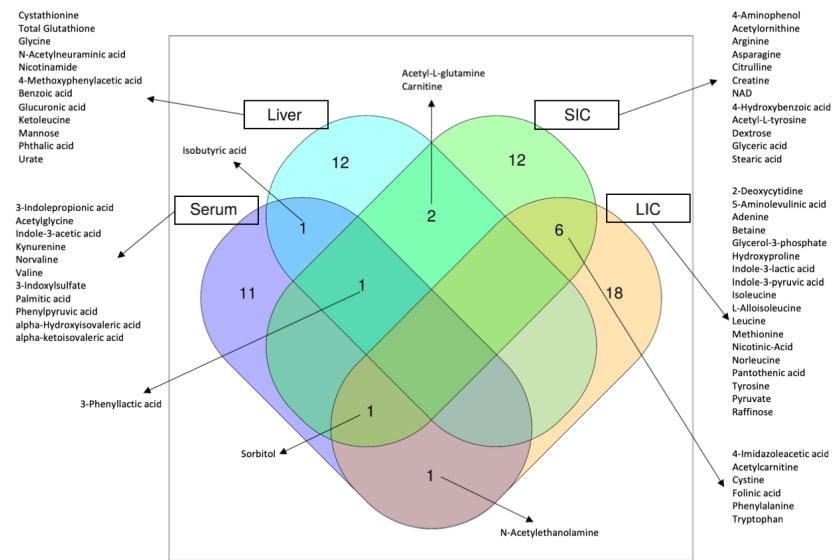

Supplemental Figure 1. Two-way hierarchical clustering dendrogram of nucleotide (A) and energy (B) metabolism genes that were significantly altered across treatment groups in liver of GF and CV mice following exposures to BDE-47 and BDE-99. Euclidian distance and complete linkage were used to generate the dendrogram. Red indicates higher standardized mean metabolite relative abundances and blue lower. Asterisks (*) represent statistically significant differences between corn oil-treated and PBDE-treated groups (adjusted p-value <0.05, Tukey's HSD post-hoc test). Caret signs (^) represent statistically significant baseline differences between CV and GF mice.

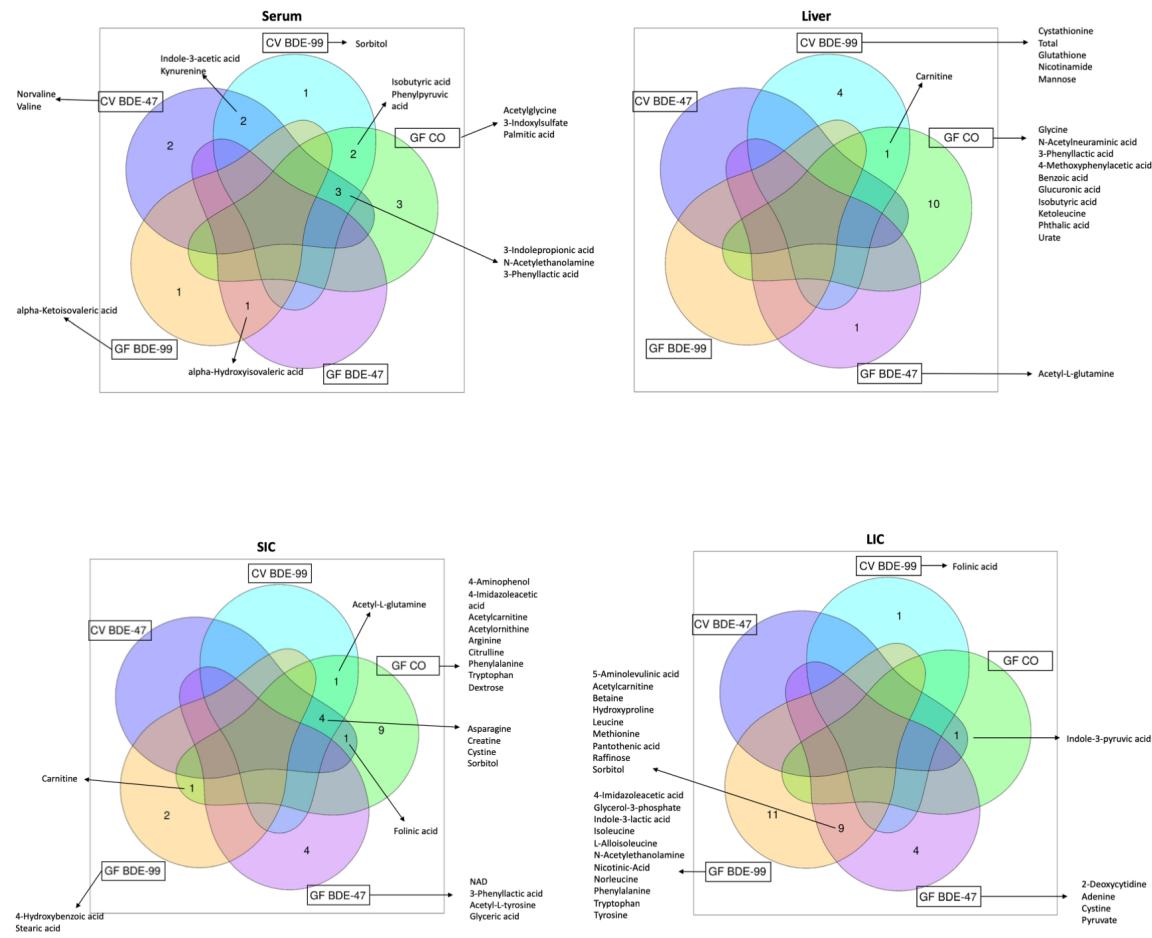

Supplemental Figure 2. Expression of Alg12 measured using RT-qPCR.

Supplemental Figure 3. Levels of glutathione measured by fluorescence (A), and LC/MS (B) shown with means and standard errors. Expression levels of Gclc and Nqo1, measured by RT-qPCR (C,E) and by RNA-Seq (D,F). Asterisks (*) represent statistically significant differences between corn oil-treated and PBDE-treated groups (adjusted p-value <0.05, Tukey's HSD post-hoc test). Caret signs (^) represent statistically significant baseline differences between CV and GF mice.

Supplemental Figure 4. Venn diagram of overlapping and uniquely differentially abundant changed metabolites across the different bio-compartments.

Supplemental Figure 5. Venn diagrams for each bio-compartment indicating overlapping and uniquely differentially abundant changed metabolites for the comparison groups (CV BDE-47 and CV BDE-99 vs CV CO, GF BDE-47 and GF BDE-99 vs GF CO, and between GF CO and CV CO mice).

Supplemental Table 1. All aqueous metabolites detected across bio-compartments.

2-3-Dihydroxybenzoic acid
2-3-Pyridinedicarboxylic acid
2-amino adipic acid
2-Deoxycytidine
2-deoxyguanosine
2-Hydroxybenzoic acid
2-Hydroxyphenylacetic acid
3-Aminoisobutyric acid
3-Hydroxykynurenone

Supplemental Table 6. Expression of genes involved in various intermediary metabolism pathways in livers of PBDE-exposed CV and GF mice. Data were obtained from RNA-Seq experiments, and average expression (FPKM) and standard errors are shown. Gene expression was calculated using Cufflinks.
