#### Abstract

Two novel homodimer metabolites were identified in rat samples collected during the in vivo study of GDC-0994. In this study, we investigated the mechanism of the formation of these metabolites. We generated and isolated the dimer metabolites using a biomimetic oxidation system for NMR structure elucidation to identify a symmetric dimer formed via carbon-carbon bond between two pyrazoles, and an asymmetric dimer formed via an aminopyrazole-nitrogen to pyrazole-carbon bond. In vitro experiments demonstrated formation of these dimers was catalyzed by cytochrome P450 enzymes with CYP3A4/5 being the most efficient. Using Density Functional Theory (DFT), we determined these metabolites share a mechanism of formation, initiated by an $\mathrm{N}-\mathrm{H}$ hydrogen atom abstraction by the catalytically active iron-oxo of CYPs. Molecular modeling studies also show these dimer metabolites fit in the CYP3A4 binding site in low energy conformations with minimal protein rearrangement. Collectively, the results of these experiments suggest that formation of these two homodimer metabolites is mediated by CYP3A, likely involving activation of two GDC-0994 molecules by a single P450 enzyme and proceeding through a radical coupling mechanism.

## Significance Statement

These studies identified structures and enzymology for two distinct homodimer metabolites, and indicate a novel biotransformation reaction mediated by CYP3A. In it, two molecules may bind within the active site and combine through radical coupling. The mechanism of dimerization was elucidated using density functional theory computations and supported by molecular modeling.

## Introduction

GDC-0994 (structure shown in Figure 1A) is a selective, potent, orally bioavailable, small molecule inhibitor of ERK1 and ERK2. It has proven anti-tumor activity in RAS- and RAF-mutant human tumor cell-line models in vitro and in vivo (Blake et al., 2016). Based on its mechanism of action and the high frequency of MAPK pathway activation in human cancers, GDC-0994 was in development as an anti-cancer therapeutic with potential in a broad array of cancer indications (Ren et al., 2015; Kirouac et al., 2017) including its clinical testing in patients with locally advanced or metastatic solid tumors (Varga et al., 2019). While thoroughly evaluating the metabolic profile of GDC-0994 in rats, the nonclinical toxicological species that supported entry into clinical development, we identified two novel dimer metabolites (M13 and M14) that formed via cytochrome P450 oxidation.

P450 enzymes catalyze a wide range of reactions for the metabolism of xenobiotics. The most common reactions include carbon hydroxylation, heteroatom oxygenation, dealkylation, and epoxidation (Ortiz de Montellano and De Voss, 2005). However, a variety of uncommon reactions by P450s have been observed. These reactions are of particular interest because their products are often not easily predicted (Guengerich and Munro, 2013). From a research perspective, these case examples provide interesting opportunities to probe the diversity of P450 function. From a drug discovery and development perspective, an unexpected metabolite adds to uncertainties and associated risks of a candidate molecule upon its first administration to human subjects (Schadt et al., 2018). Therefore, understanding reaction mechanisms, structural requirements, and specific isoform(s) responsible for these reactions is critical to anticipate and mitigate metabolic liabilities.

Of the P450 isoforms found in humans, CYP3A4 is most frequently identified as the principle metabolizing enzyme of approved drugs (Cerny, 2016). CYP3A4 has a large and flexible
active site that accommodates a variety of ligands, including large substrates such as cyclosporine A (molar mass $1203 \mathrm{~g} / \mathrm{mol}$ ). Understanding the diversity of reactions that CYP3A4 can catalyze provides a foundation to understand the breadth of possible metabolic products it can generate and feed back to the design and optimization of new molecular entities.

In this report, we describe the identification and structure determination of two distinct homodimers of GDC-0994 and provide in vitro evidence that CYP3A catalyzed their formations. We also embarked on a computational study using density functional theory (DFT) to determine the likely mechanism of dimer formation and molecular modeling to evaluate the feasibility of dimer formation within CYP3A4.

## Materials and Methods

## Chemicals and Reagents

[ $\left.{ }^{14} \mathrm{C}\right]$ GDC-0994 was synthesized by Selcia Limited (Essex, UK) with radiochemical purity $>98.5 \%$ (specific activity $52.23 \mathrm{mCi} / \mathrm{mmol}$ ) and non-radiolabeled GDC-0994 was synthesized at Genentech (South San Francisco, CA). Liver microsomes and recombinant P450 enzymes were purchased from BD Gentest (San Jose, CA) or Bioreclamation IVT (Westbury, NY). Horseradish peroxidase was obtained from Sigma-Aldrich (St Louis, MO). Myeloperoxidase from human leukocytes was purchased from EMD Millipore Co. (Temecula, CA). All chemical reagents and solvents were purchased from commercial sources at the highest purities possible.

## In Vivo Metabolite Identification Study

Male and female Sprague-Dawley rats were orally administrated with a single dose of $\left[{ }^{14} \mathrm{C}\right]$ GDC-0994 at $50 \mathrm{mg} / \mathrm{kg}(100 \mu \mathrm{Ci} / \mathrm{kg})$ in $1 \%$ carboxymethylcellulose, $0.5 \%$ Tween, and 5 mM citrate solution. In vivo study design, sample collection and radioanalysis were provided in

Supplemental Materials. Metabolite profiling and identification was performed using liquid chromatography coupled with simultaneous radiodetection and high-resolution mass spectrometric analysis. Method details are also provided in Supplemental Materials.

## Metabolite Generation using Biomimetic Enzymes

BMO $^{\text {TM }}$ Production Kit (HCK1001-03-027-A7-10) (HepatoChem Inc, Beverly, MA) was used to generate, scale up and isolate two metabolites of interest, M13 and M14. Standard protocols provided by the vendor were followed for screening, optimization, and production of metabolites. The incubations were performed with 6.25 mM of GDC-0994 free base. The dimer metabolites were purified by semi-preparative HPLC using a Hypersil Gold C18 column (150 x $10 \mathrm{~mm}, 5 \mu \mathrm{~m}$ particle size, Thermo Scientific, San Jose, CA) with mobile phases of $0.1 \%$ formic acid in water and acetonitrile at a constant flow rate of $4.6 \mathrm{ml} / \mathrm{min}$. The incubation products were separated by gradient elution and fractions were collected and surveyed by LC-MS for the analytes of interest. The fractions containing M13 and M14 were then separately combined and evaporated to dryness under vacuum.

## Structure Determination by NMR

All NMR experiments were collected on an Avance II spectrometer (Bruker BioSpin, Billerica, MA) operating at 500 MHz for ${ }^{1} \mathrm{H}, 125 \mathrm{MHz}$ for ${ }^{13} \mathrm{C}$ equipped with 5 mm TCI cryoprobe with Z-gradient. Each metabolite sample was dissolved in $180 \mu \mathrm{~L}$ of DMSO-d6 (Cambridge Isotope Labs, Tewksbury, MA). 1D ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR were collected at ambient temperature and 335 K , respectively. Chemical shifts were referenced to tetramethylsilane at $\delta=0 \mathrm{ppm}$. 2D COSY, HSQC, HMBC, ROESY were collected at 335K.

## In Vitro Metabolism

GDC-0994 ( $10 \mu \mathrm{M}$ ) was incubated with liver microsomes (male rat, female mouse, male beagle dog, male cynomolgus monkey or 200 mixed sex donor pooled human, $0.5 \mathrm{mg} / \mathrm{mL}$ ) in potassium phosphate buffer ( $100 \mathrm{mM}, \mathrm{pH} 7.4$ ) containing magnesium chloride ( 3 mM ) supplemented with 1 mM NADPH in an incubation volume of 0.5 mL . Incubations with individually expressed recombinant P450 enzymes (Supersomes) were completed similarly with GDC-0994 ( $1 \mu \mathrm{M}$ ) and a constant amount of P450 (40 pmol/mL). Inhibition experiments were conducted with human liver microsomes using standard concentrations of P450 isoform-selective chemical inhibitors: ABT (1 mM, pan-P450), furafylline (10 $\mu \mathrm{M}$, CYP1A2), 2-phenyl-2-(1piperidinyl)propane ( $20 \mu \mathrm{M}$, CYP2B6), montelukast ( $2 \mu \mathrm{M}$, CYP2C8), sulfaphenazole ( $10 \mu \mathrm{M}$, CYP2C9), 3-benzylnirvan ( $2 \mu \mathrm{M}$, CYP2C19), quinidine ( $1 \mu \mathrm{M}$, CYP2D6), ketoconazole ( $1 \mu \mathrm{M}$, CYP3A4) or troleandomycin (20 $\mu \mathrm{M}$, CYP3A4). In the incubations with ABT and troleandomycin, HLM was preincubated with inhibitors for 15 min before GDC-0994 was added to the incubations. At the end of incubation, reactions were stopped, and proteins were removed by adding acetonitrile and centrifuging.

GDC-0994 (100 $\mu \mathrm{M}$ ) was incubated with horseradish peroxidase (40 units/mL), $\mathrm{NaCl}(150$ $\mathrm{mM}), \mathrm{H}_{2} \mathrm{O}_{2}(100 \mu \mathrm{M})$ in 100 mM phosphate buffer pH 7.4 at $37^{\circ} \mathrm{C}$ for 1 hour. GDC-0994 (100 $\mu \mathrm{M})$ was separately incubated with myeloperoxidase ( $0.1 \mathrm{mg} / \mathrm{mL}$ ), $\mathrm{NaCl}(150 \mathrm{mM}), \mathrm{H}_{2} \mathrm{O}_{2}$ (100 $\mu \mathrm{M})$ in 100 mM phosphate buffer pH 6.0 at $37^{\circ} \mathrm{C}$ for 1 hour. Reactions were quenched with 3 volumes of acetonitrile. The supernatant was diluted with 3 volumes of water and injected for LCMS analysis.

## Computational Methods

All DFT computations were performed using Gaussian09 (Frisch et al., 2013). Geometry optimizations and frequency calculations were performed at the B3LYP (Becke, 1993) level using

LANL2DZ for Fe and $6-31 \mathrm{G}(\mathrm{d})$ on all other atoms. Frequencies were used to check for the presence of a local minimum (zero negative frequencies) or a transition structure (exactly one negative frequency, corresponding to the desired transformation). Frequencies were also used to compute enthalpy and free energy corrections at a standard state of 1 atm and 298.15 K . An additional correction for entropy was used to apply a quasiharmonic approximation, as discussed by Truhlar (Zhao and Truhlar, 2008; Ribeiro et al., 2011). Single point energy calculations were computed for each structure at the B3LYP-D3(BJ) (Grimme et al., 2011) level using LANL2DZ for iron and 6-311+G(d,p) on all other atoms and the SMD (Marenich et al., 2009) implicit solvent models for water. The corresponding energies and correction factors for calculation of zero-point energy (ZPE), enthalpy, and entropy of each of the coordinates are provided in the Supplemental Materials.

## Molecular Modeling

Molecular modeling studies were performed using MOE (Chemical Computing Group ULC, 2018) with the MMFF94x forcefield (Halgren, 1996d; Halgren, 1996b; Halgren, 1996a; Halgren, 1996c; Halgren and Nachbar, 1996; Halgren, 1999b; Halgren, 1999a) and docking was performed with Glide (Schrödinger LLC, 2016). Conformational analyses of the dimer structures were performed with the sdfMMConfAnalysis module of the Chemalot software package (Lee et al., 2017).

## Results

## Identification of Metabolites

GDC-0994 was extensively metabolized in rats (Supplemental Figure S1). A total of 14 metabolites were tentatively identified (Supplemental Figure S2), primarily consisting of
oxidation, $N$-dealkylation, glucuronidation, or a combination of these reaction. Two distinct radiopeaks, M13 and M14, which eluted later than unchanged GDC-0994, were observed in bile and feces profiles (Supplemental Figure S1). The protonated molecular ions observed to M13 and M14 were identical ( $\mathrm{m} / \mathrm{z} 879.2343, \mathrm{C}_{42} \mathrm{H}_{35} \mathrm{~N}_{12} \mathrm{O}_{4} \mathrm{Cl}_{2} \mathrm{~F}_{2}(-0.1 \mathrm{ppm})$ ), which corresponded to two molecules of GDC-0994 connected by loss of two hydrogens, suggesting they are homodimer metabolites. The MS ${ }^{2}$ and MS ${ }^{\text {n }}$ product ion spectra of GDC-0994, M13 and M14 are shown in Figure 1. M13 and M14 shared highly similar MS ${ }^{2}$ and MS ${ }^{3}$ fragmentation spectra (Figure 1b and 1c), which showed product ions at $m / z 707$ (loss of chloro fluoro phenyl ethanol), $m / z 689$ (loss of water from $m / z$ 707), and $m / z 535$ (loss of chloro fluoro phenyl ethanol from $m / z 707$ ). However, their $\mathrm{MS}^{4}$ spectra were dramatically different; implying the connectivity of the dimers was the structural distinction between M13 and M14. In addition, heterodimers composed of one unit of GDC-0994 and one unit of the $N$-desmethyl metabolite (M12) were only detected in bile by mass spectrometry in significantly lower quantities than M13/M14. Homodimers of M12 were not detected in any matrices, presumably due to its low overall concentration.

## Dimer Metabolite Generation and Structure Elucidation

To fully characterize the structures of the proposed GDC-0994 dimers, we attempted to scale up the metabolites with various in vitro systems. The product yields in microsomal or expressed P450 incubations were too low to efficiently obtain sufficient amounts of product. Thus, metabolite generation was surveyed and scaled using organometallic catalysis purchased from HepatoChem. This tool provides biomimetic catalysts to mimic the suite of P450 enzymes present in human hepatocytes, offering the researcher a unique approach to quickly find reaction conditions that generate target drug metabolites and scale them to provide sufficient quantities for structural characterization or pharmacological potency testing (Chen and White, 2007; Cusack et

DMD \# 90019
al., 2013). From the biomimetic screening panel, M13 and M14 were generated to greatest extent by metalloporphyrin FeTDCIPP and $\mathrm{H}_{2} \mathrm{O}_{2}$ as oxidant. This catalytic system was scaled up to generate sufficient quantities of metabolites for isolation by chromatography and fractionation for definitive structure characterization by NMR.

Based on NMR studies, M13 is a symmetrical dimer while M14 is an asymmetrical dimer of GDC-0994 (Figure 2). At room temperature, proton NMR spectra of both M13 and M14 showed broad resonances due to restricted rotation. Thus, both M13 and M14 were heated to 335K to obtain well resolved 1D proton NMR and 2D data. Proton NMR of M13 gave only one set of resonances, which was comparable to those observed for GDC-0994. The distinct differences were one pyrazole proton H 16 at 6.3 ppm was missing and the other pyrazole proton H 17 became singlet by losing coupling with H16. There was also an extra quaternary carbon on carbon-13 NMR of M13. These structural features were consistent with two GDC-0994 molecules forming a symmetrical dimer at C16 position. The new carbon-carbon bond formed in M13 was labeled as C16-C47. For M14, proton NMR gave two sets of resonances consistent with GDC-0994 with two resonances missing, one pyrazole proton H16 from one GDC-0994 molecule and NH from another GDC-0994 molecule. This evidence concludes that a carbon-nitrogen bond was formed between two GDC-0994 molecules to give an asymmetrical dimer with same molecular weight as M13. The new carbon-nitrogen bond formed in M14 labeled as C16-N45.

## In Vitro Formation of Dimer Metabolites

In vitro studies demonstrated dimer formation with liver microsomal incubations for rats, mice, rabbits, dogs, monkeys, and humans, albeit all to low extent. With human liver microsomes, the formations of the dimers were time and NADPH-dependent, and abolished when P450 enzymes were inactivated by preincubating with ABT or ketoconazole, pan-P450 and CYP3A
inhibitors, respectively (Supplemental Figure S3). Incubations with singly expressed recombinant P450s showed CYP3A4 and 3A5 were the most productive in generating M13 and M14.

Incubations of GDC-0994 with horseradish peroxidase in the presence of $\mathrm{Cl}^{-}$and $\mathrm{H}_{2} \mathrm{O}_{2}$ produced both M13 and M14 with less than 5\% yield (Supplemental Figure S4), providing evidence of a radical initiation of the mechanism. Dimers were not detected in the incubations of GDC-0994 with myeloperoxidase.

## Mechanism of Dimer Metabolite Formation

Density functional theory was used to computationally evaluate two mechanisms of dimer formation (Figure 3, Pathways A and B), using a truncated model of GDC-0994 (X). Computations show that the preferred mechanism (Figure 4) is Pathway B, involving dual radical formation followed by radical coupling. Pathway A is disfavored due to the high energetics of radical addition to a neutral monomer (Figure 5).

Docking of either dimer product (M13 or M14) to CYP 3A4 (PDB code 6BD5) did not yield reasonable substrate poses. Suspecting the protein conformation captured in the crystal structure does not adequately capture the flexibility of the binding pocket, we built custom models for each dimer/protein complex using a protocol similar to that described by Hayes and coworkers (Hayes et al., 2014). Binding pocket residues of the enzyme were mutated to alanine (details in Supplemental Information) and the core of each dimer structure ( $\mathbf{X}_{\mathbf{1}} \mathbf{X}_{\mathbf{2}}$ in Figure 3 and the N -linked dimer analogue) were positioned such that the dimer bond was in proximity of the iron-heme. We then gradually and iteratively grew each ligand to its full form in the active site by: (1) adding compound substituents to the core in conformations that avoided steric clashes with the backbone and mutated residues of the protein; (2) minimizing the resulting ligand in situ; (3) removing the protein and the minimizing the ligand in vacuo to remove ligand strain; (4) re-introducing the
protein and minimizing side chains and backbone with harmonic constraints in the presence of the fixed ligand. After the dimer structures were completely assembled, the mutated sidechains were restored to the native structure in rotamer states that accommodated the dimer-protein complex. Lastly, each completed and restored complex was minimized one additional time to produce the final models (Figure 6). The final models had minor differences from the original PDBs, with RMSD values of $1.1 \AA$ and $0.48 \AA$ for the CYP3A4-M13 complex and CYP3A4-M14 complex, respectively. Both M13 and M14 are in low-energy conformational states within the complexes ( $<2 \mathrm{kcal} / \mathrm{mol}$ from the conformational global energy minimum), so ligand strain is minimal.

## Discussion

The P450-mediated bioactivation of a small molecule to generate a radical reactive intermediate and initiate dimerization was an unexpected biotransformation route. Some preceding examples of similar reactions have been described in the literature and diverse mechanistic routes for dimer formation have been proposed. Gillam and coworkers reported P450-mediated oxidation of indole to indoxyl, which was subsequently oxidized and dimerized to form indigoids (Gillam et al., 2000; Isin and Guengerich, 2007). Two diastereoisomeric thiophene $S$-oxide dimers were observed in thiophene metabolism in vitro and in vivo in rats, where the combination of molecules was rationalized to occur via a Diels-Alder reaction (Treiber et al., 1997). Similar dimerization was reported for ticlodipine (Dansette et al., 2005). Dimerization through free radical intermediates has been described for capsaicin and CJ-047710 (Emoto et al., 2007; Reilly et al., 2013). Homodimerization of raloxifene was also reported to occur via a CYP3A4-mediated oxidative reaction (Davis et al., 2011). Several overlaps exist in the observations for CJ-047710, raloxifene, and GDC-0994, suggesting these dimerization reactions may share common mechanistic features.

After identifying that the dimers of GDC-0994 were formed via CYP3A4 using standard in vitro techniques, we sought to determine the mechanism of their formation to glean a deeper understanding of how these and other dimers are formed.

Two possible mechanisms for the formation of the observed dimers were evaluated with density function theory (DFT) (Pathways A and B, Figure 3). Aromatic C-H abstraction is not a part of either proposed mechanism. C-H hydrogen abstraction from pyrazole was ruled unfavorable given the high bond dissociation energies (BDE) of the C-H bonds, which were previously computed to be between 118.7 and $122.2 \mathrm{kcal} / \mathrm{mol}$ (Feng et al., 2003). In contrast, the BDE for aniline N-H has been computed to be significantly lower at $91.4 \mathrm{kcal} / \mathrm{mol}$ (Song et al., 2003). The proposed mechanisms in Figure 3 are consistent with existing precedence for P450mediated aromatic couplings (Isin and Guengerich, 2007; Makino et al., 2007; Woithe et al., 2007; Belin et al., 2009; Grandner et al., 2016).

Both pathways A and B initiate with N-H abstraction from model substrate $\mathbf{X}$ by the ironoxo complex for $\mathbf{P} 450(\mathbf{c p d} \mathbf{I})$ to provide a radical species $\left(\mathbf{X}_{\mathbf{1}}{ }^{\bullet}\right)$ and iron-hydroxo (cpd II). This radical species $\left(\mathbf{X}_{\mathbf{1}}{ }^{\bullet}\right)$ is delocalized between the nitrogen and other atoms in conjugated pyrazole via resonance, and thus the radical can form a new bond from the initial nitrogen involved in the abstraction or carbon in the pyrazole ring. For subsequent steps in Figure 3, only C-C coupling is shown for simplicity but $\mathrm{C}-\mathrm{N}$ coupling is proposed to occur in the same manner. In Pathway A, radical addition of $\mathbf{X}_{\mathbf{1}} \cdot{ }^{\cdot}$ to $\mathbf{X}_{\mathbf{2}}$ occurs and subsequent $\mathrm{N}-\mathrm{H}$ abstraction by $\mathbf{c p d I I}$ from $\mathbf{X}_{\mathbf{1}} \mathbf{X}_{\mathbf{2}}{ }^{\cdot}$ forms the final product. The alternate Pathway B describes forming a second radical species ( $\mathbf{X}_{\mathbf{2}}{ }^{\circ}$ ) via N H abstraction, facilitated by $\mathbf{c p d} \mathbf{I I}$, and radical coupling of $\mathbf{X}_{\mathbf{1}}{ }^{\cdot}$ and $\mathbf{X}_{\mathbf{2}}{ }^{\circ}$ for the formation of the final dimer product. Thus, Pathways A and B both describe two hydrogen abstraction steps and a coupling reaction but only diverge in the order of the reaction steps.

The proposed mechanisms were computed using DFT and compared to determine the intrinsically favored pathway (Figure 4). N -H abstraction by $\mathbf{c p d} \mathbf{I}$ from $\mathbf{X}_{\mathbf{1}}$ has a barrier of only $6.7 \mathrm{kcal} / \mathrm{mol}$ (2-TS, Figure 4). This very low barrier indicates abstraction would occur rapidly at room temperature upon appropriate substrate binding. For radical additions of $\mathbf{X}_{\mathbf{1}}{ }^{\bullet}$ to ground-state $\mathbf{X}_{2}$ (Pathway A) to form either C-N or C-C coupled product are $>30 \mathrm{kcal} / \mathrm{mol}$ and prohibitively high at room temperature (Figure 5). Accounting for reduced entropic costs due to precomplexation of $\mathbf{X}_{\mathbf{1}}{ }^{\cdot}$ and $\mathbf{X}_{\mathbf{2}}$ to CYP3A, this barrier is still rather high and indicates a disfavoring of this radical addition. In the subsequent steps for Pathway B (Figure 4), ligand exchange to allow the $\mathrm{N}-\mathrm{H}$ of $\mathbf{X}_{2}$ to coordinate to the iron-hydroxo $\mathbf{~ c p d ~ I I , ~ f o r m e d ~ b y ~ t h e ~ f i r s t ~ a b s t r a c t i o n , ~ i s ~ f a v o r e d ~}$ by $>5 \mathrm{kcal} / \mathrm{mol}$ (3 to 4, Figure 4). N-H abstraction from $\mathbf{X}_{2}$ by $\mathbf{~ c p d ~ I I ~ i s ~ n e a r l y ~ b a r r i e r - l e s s ~ a t ~} 1$ $\mathrm{kcal} / \mathrm{mol}$ (4 to 5-TS, Figure 4). This barrier is low due to the release of water in the transition state. Radical combination of the delocalized radicals after formation via the two hydrogen abstractions would be rapid further facilitated by the forced close proximity in the active site. The mechanism is the same for each metabolite as formation of the two distinct products is facilitated by the delocalized nature of the radicals formed from $\mathrm{N}-\mathrm{H}$ abstraction ( $\mathbf{X}_{\mathbf{1}}{ }^{\circ}$ and $\mathbf{X}_{\mathbf{2}}{ }^{\circ}$ ).

The molecular modeling studies generated two dimer-CYP3A4 structures that indicate that M13 or M14 formation within the active site of the enzyme is sterically feasible with minimal rearrangement of the protein (Figure 6). While we do not claim that these models are definitive binding modes, they provide supportive evidence for the mechanism we propose for homodimer formation.

In summary, during the in vivo metabolite profiling of GDC-0994 in rats, we discovered two novel dimer metabolites. In vitro studies indicated these metabolites were generated across several animal species and human, with CYP3A4/5 being the most effective. Biomimetic catalysis

DMD \# 90019
produced sufficient quantities of the metabolites to resolve the structures and lead to the identification of a symmetrical and asymmetrical homodimer. Computational studies determine that the dimers likely form via tandem N-H abstractions from monomer GDC-0994 units and subsequent radical coupling. Molecular modeling indicates that the CYP3A4 pocket is large and flexible enough to accommodate the dimer in the active site. All together, these studies provide evidence that large dimers can be formed by P450s and the mechanistic analysis can inform other drug discovery programs dealing with metabolism of similar substrates.

## Supplemental Methods

In Vivo Study. Male and female nonsurgicalized and bile duct-cannulated (BDC) SpragueDawley rats ( $\mathrm{n}=3$ per group) were orally administered a single dose of $\left[{ }^{14} \mathrm{C}\right]$ GDC-0994 at 50 $\mathrm{mg} / \mathrm{kg}(100 \mu \mathrm{Ci} / \mathrm{kg})$ in $1 \%$ carboxymethylcellulose, $0.5 \%$ Tween, and 5 mM citrate solution. BDC rats were supplemented with an infusion of taurocholic acid ( $2.3 \mathrm{mg} / \mathrm{ml}$ in $0.9 \%$ saline) via the distal (duodenal) cannula. Urine and bile were collected on dry ice at approximately $0-8 \mathrm{~h}, 8-24 \mathrm{~h}$, and then at 24 -h intervals. Feces were collected on dry ice at intervals of 24 h up to 168 and 96 hours postdose from intact and BDC rats, respectively, and homogenized with 3-5 volumes of $50 \%$ (by volume) aqueous isopropyl alcohol. Plasma samples at 0 hour (predose) and at $1,2,4,8$, and 24 hours post-dose were also collected from another group of male and female rats for metabolite profiling.

Radioactivity Analysis. Total radioactivity in each matrix was measured by LSC analyses using a Model 2800TR analyzer (Perkin Elmer) with counting for 5 min . Plasma ( $\sim 0.1 \mathrm{~mL}$ ), urine ( $\sim 0.3$ $\mathrm{ml})$ or bile ( $\sim 0.1 \mathrm{ml}$ ) were mixed with Ultima Gold scintillation cocktail ( 5 mL ) for radio counting. Fecal homogenates ( $\sim 0.5 \mathrm{~g}$ ) were dried and combusted in a Model 307 sample oxidizer (Perkin Elmer) and the resulting ${ }^{14} \mathrm{CO}_{2}$ was trapped in CarboSorb and Perma-Fluor scintillation cocktail was added for LSC counting.

Sample Preparation for Metabolite Profiling. Urine, bile, and feces were pooled with an equal percentage of the weight or volume collected to give a single sample that represented $>95 \%$ of the radioactivity eliminated by each excretion route. Pooled urine and bile samples ( $\sim 0.4 \mathrm{ml}$ ) were centrifuged, and the supernatants were injected directly for metabolite profiling. Plasma samples $(1 \mathrm{~mL})$ were extracted twice with three volumes of acetonitrile. Fecal samples ( $\sim 1 \mathrm{~g}$ ) were extracted three times with CAN. The extracts were combined, evaporated to dryness by an N -

Evaporator (Caliper Life Sciences, Hopkinton, MA), and reconstituted in $500 \mu \mathrm{~L}$ of $\mathrm{ACN} / \mathrm{H}_{2} \mathrm{O}$ ( $\mathrm{v} / \mathrm{v}, 1: 3$ ).

LC-MS/MS and Radioprofiling of Metabolites. Chromatography was performed on a Kinetex XB C18 column ( $150 \times 4.6 \mathrm{~mm}, 2.6 \mu \mathrm{~m}$ particle size, Phenomenex, Torrance, CA) with mobile phases A ( $0.1 \%$ formic acid in water), and B (acetonitrile), at a constant flow rate of $1 \mathrm{ml} / \mathrm{min}$. The gradient was as follows: initial holding at $10 \%$ B for 5 min , increased to $25 \% \mathrm{~B}$ at $20 \mathrm{~min}, 35 \% \mathrm{~B}$ at $40 \mathrm{~min}, 40 \%$ at $41 \mathrm{~min}, 45 \%$ at 50 min , and $95 \%$ B at 54 min , holding until 57 min and then column re-equilibration. The flow was split 10:1 post-column for radio-measurements and mass spectrometry, respectively. Radio-measurements were completed via fractionation to Deepwell LumaPlate 96 microplates (PerkinElmer) (10s per fraction), evaporation of solvents under vacuum, then counting radioactivity on the plates using a TopCount NXT scintillation and luminescence counter (PerkinElmer) for 5 min at $20^{\circ} \mathrm{C}$. Radioprofiles were reconstructed and integrated using the LSC import function in Laura software (LabLogic Systems; Brandon, FL). Mass spectrometric measurements were made with high resolution accurate mass full scan and tandem mass spectrometry (MS) experiments with an LTQ-Orbitrap with a heated electrospray ionization source (Thermo Scientific, San Jose, CA). The electrospray voltage was set at 4.0 kV and capillary temperature was $270^{\circ} \mathrm{C}$. The full-scan mass spectra were obtained at resolving power of 30,000 and corresponding data dependent $\mathrm{MS}^{\mathrm{n}}$ scans following collision induced dissociation were acquired at a resolving power of 7,500 .

## Molecular Modeling Details

A survey of structures in the protein databank revealed that the structure with PDB code 6BD5 had the largest binding pocket volume of all CYP 3A4 structures (Michael Drummond, personal communication). A protein structure with a larger binding site volume was created by mutating residues bordering the binding site (Hayes et al., 2014). Residues that had a heavy atom within $4.5 \AA$ of the native ligand in the 6BD5 structure were mutated to alanine (residues affected: R105 F107 S119 I120 R212 F213 F215 F241 I301 F304 A305 T309 A370 R372 L373 E374).

Following the creation of the bound ligand protein complexes through iterative growth and structure relaxation as described in the main text, the final protein structures did not deviate significantly from the original structure. For protein $\mathrm{C} \alpha$ atoms that were within $10 \AA$ of either modeled dimer (i.e, the $\alpha$-carbons near the binding site), the root mean square deviation between their positions in the original CYP3A4 structure and those of the current models were $1.1 \AA$ (CYP3A4-M13) and $0.48 \AA$ (CYP3A4-M14). The difference between the two is presumably due to a more globular shape to M13, which requires greater protein motion to fit in the CYP3A4 pocket compared to M14.

## Supplemental Figures

Figure S1. Radiochromatogram of male AUC 0 -8h pooled plasma, 0 to 48 hour pooled urine, bile and 0 to 72 hour pooled feces samples

Figure S2. Proposed metabolic pathways of GDC-0994 in rats

Figure S3. (a) Extracted ion chromatogram of GDC-0994, M13 and M14 from the incubation of (a) GDC-0994 with human liver microsomes and NADPH, (b) GDC-0994 with human liver microsomes and NADPH after a preincubation with ABT, a pan P450 inhibitor, and (c) GDC0994 with human liver microsome and NADPH after a preincubation with ketoconazole, a selective CYP3A inhibitor.

Figure S4. (a) Extracted ion chromatogram of GDC-0994, M13 and M14 from the incubation of GDC-0994 with horseradish peroxidase. (b) MS ${ }^{2}$ and MS ${ }^{3}$ product ion spectra of M13
