ABSTRACT

Despite peptide transporter 1 (PEPT1) being responsible for the bioavailability for a variety of drugs, there has been little study of its potential involvement in drug-drug interactions. Pomaglometad methionil, a metabotropic glutamate 2/3 receptor agonist prodrug, utilizes PEPT1 to enhance absorption and bioavailability. In vitro studies were conducted to guide the decision to conduct a clinical drug interaction study and to inform the clinical study design. In vitro investigations determined the prodrug (LY2140023 monohydrate) is a substrate of PEPT1 with K_m value of approximately 30 μ M, whereas the active moiety (LY404039) is not a PEPT1 substrate. In addition, among the eight known PEPT1 substrates evaluated in vitro, valacyclovir was

the most potent inhibitor ($IC_{50} = 0.46$ mM) of PEPT1-mediated uptake of the prodrug. Therefore, a clinical drug interaction study was conducted to evaluate the potential interaction between the prodrug and valacyclovir in healthy subjects. No effect of coadministration was observed on the pharmacokinetics of the prodrug, valacyclovir, or either of their active moieties. Although in vitro studies showed potential for the prodrug and valacyclovir interaction via PEPT1, an in vivo study showed no interaction between these two drugs. PEPT1 does not appear to easily saturate because of its high capacity and expression in the intestine. Thus, a clinical interaction at PEPT1 is unlikely even with a compound with high affinity for the transporter.

Introduction

Pomaglometad methionil (LY2140023 monohydrate), a potent and selective methionil prodrug of the metabotropic glutamate 2/3 (mGlu2/3) receptor agonist LY404039 (the active moiety) (Monn et al., 2005), was developed to use the intestinal peptide transporter 1 (PEPT1; SLC15A1) to enhance the bioavailability of the active moiety (Patil et al., 2007). The orally administered prodrug is rapidly absorbed in the intestine and hydrolyzed to the active moiety (Fig. 1) with no further known metabolism (Moulton et al., 2015). PEPT1 is highly expressed at the apical membrane of enterocytes in the small intestine and uses the inwardly directed proton gradient to move substrates across the cell membrane (Daniel and Kottra, 2004; Brandsch et al., 2008). This inwardly directed proton gradient is maintained by an acidic microenvironment in intestinal epithelia. The intervillous pH at the intestinal epithelia ranges from 6.1 to 6.6, whereas intracellular pH of enterocyte is approximately 7.3 (Brandsch et al., 2008). In addition to di- and tri-peptides, PEPT1 has been shown to transport a variety of chemically diverse compounds such as angiotensin converting enzyme inhibitors (captopril and enalapril), β -lactam antibiotics (cefadroxil and cephalixin), and valacyclovir, the prodrug of acyclovir. Given its broad

substrate specificity and high capacity, targeting PEPT1 has become a strategy in drug development for improving poor intestinal absorption. For example, acyclovir bioavailability was significantly increased after the introduction of an ester linkage to valine resulting in the PEPT1 substrate, valacyclovir (Ganapathy et al., 1998).

PEPT1 is highly expressed in the intestines, brain, and kidney. Within the intestines, PEPT1 expression is localized in the duodenum, ileum, and jejunum of mice (Groneberg et al., 2001; Jappard et al., 2010) and humans (Walker et al., 1998; Groneberg et al., 2001). Recent proteomic data showed that PEPT1 is the most abundantly expressed transporter in the intestines (Drozdik et al., 2014), with higher expression than apical uptake transporters such as organic anion transporting polypeptide 2B1 (OATP2B1/SLCO2B1) and apical sodium/bile acid cotransporter (ASBT/SLC10A2), and apical efflux transporters such as P-glycoprotein/ABCB1, breast cancer resistance protein (BCRP/ABCG2), and the multidrug resistance-associated proteins (MRPs/ABCCs).

Because PEPT1 is considered to be a low-affinity and high-capacity transporter with K_m values ranging typically from high micromolar to low millimolar for most of marketed PEPT1 substrates, there is no major concern of an interaction between drugs transported by PEPT1 during absorption (Hillgren et al., 2013). Phan and colleagues (2003) observed no statistically different changes in acyclovir AUC when valacyclovir was administered alone or co-dosed with cephalixin. However, potential for interaction cannot be ruled out if a high-affinity PEPT1 substrate is

Financial support for this study was provided by Eli Lilly and Company.

ABBREVIATIONS: AE, adverse event; ALA, 5-aminolevulinic acid; AUC, area under the curve; BCRP, breast cancer resistance protein; CI, confidence interval; C_{max} , maximum concentration; DDI, drug-drug interaction; DOPA, dihydroxyphenylalanine; GI, gastrointestinal; Gly-Sar, glycylsarcosine; LLQ, lower limit of quantification; SM, least squares means; mGlu2/3, metabotropic glutamate 2/3; NMEs, new molecular entities; PEPT1, peptide transporter 1; P-gp, P-glycoprotein; PK, pharmacokinetics; SM, least squares means; ULQ, upper limit of quantification.

Fig. 2. Time- and pH-dependent accumulation of [^{14}C]LY2140023 (30 μM) and [^{14}C]LY404039 (30 μM). The experiments were conducted using HeLa cells transiently transfected with either PEPT1 or empty vector. The reactions were performed using buffer at either pH 6.0 or 7.5. The cells were incubated with either LY2140023 or LY404039 from 1 to 15 minutes at room temperature. Each symbol represents the mean of two wells per each time point and treatment in 24-well plate.

A sufficient number of subjects were enrolled to obtain 18 subjects to complete the study. This sample size was to provide at least 90% power to show the inclusion of the 90% confidence intervals (CI) of the ratio of area under the curve (AUC) geometric means between the test (LY2140023 + valacyclovir) and reference (LY2140023 alone) fall within the interval (0.80, 1.25).

Bioanalysis. Plasma samples were analyzed for valacyclovir, acyclovir, LY2140023 (prodrug), and LY404039 (active moiety) using validated turbo ion spray liquid chromatography/tandem mass spectrometric methods. For the prodrug and active moiety, the lower limit of quantification (LLQ) was 0.25 ng/ml and the upper limit of quantification (ULQ) was 100 ng/ml for both analytes (Annes et al., 2015). For valacyclovir and acyclovir, the LLQ was 100 ng/ml and the ULQ was 1000 ng/ml for both analytes.

Urine samples were analyzed for valacyclovir, acyclovir, and/or active moiety using a validated liquid chromatography/tandem mass spectrometric method. No analysis of the prodrug was performed because previous studies have shown that it is not excreted in the urine. For the active moiety, the LLQ was 50 ng/ml and the ULQ was 5000 ng/ml. For valacyclovir and acyclovir, the LLQ was 100 ng/ml and the ULQ was 20,000 ng/ml.

For all bioanalytical methods, samples above the limit of quantification were diluted and reanalyzed to yield results within the calibrated range.

Pharmacokinetic Analyses. Plasma concentration-time data for valacyclovir, acyclovir, LY2140023, and LY404039 were analyzed by standard noncompartmental methods of analysis using WinNonlin Version 5.3. Actual sampling times were used in the analyses with the exception of predose times, which were set to 0 hour. Area under the curve (AUC) values were determined using log-linear trapezoid methods. When calculating CL/F and Vz/F for the active moiety, the dose of the prodrug was adjusted based on the molar ratio of active moiety to prodrug (0.64).

Urine concentration and volume data were measured for LY404039, valacyclovir, and acyclovir. Amounts excreted over each collection interval were summed to determine the cumulative amount excreted over the 24-hour collection interval [Ae(0–24)]. The fraction of the dose excreted (fe) was also determined. For the active moiety dose, the 0.64 correction factor was used as described previously. Similarly, for acyclovir, the valacyclovir dose was adjusted based on the molar ratio of acyclovir to valacyclovir (0.694). Apparent renal clearance was estimated using the cumulative amount excreted up to the last collection interval and plasma AUC(0–24).

Although PK parameters were determined for all subjects with concentration-time data, if vomiting occurred within 5 hours postdose the concentration-time data and PK parameters from that dosing period were not included in any data summaries or statistical analysis. Only one subject (in Period 2) had PK data excluded because of vomiting.

The primary PK parameters (C_{max} and AUC) for LY2140023, LY404039, valacyclovir, and acyclovir were compared when the prodrug and valacyclovir were administered alone and in combination. AUC(0– ∞) was used for all analytes except valacyclovir where AUC(0–3) was assessed. Parameters were compared using linear mixed effect model where treatment (80 mg of LY2140023 administered alone, 1000 mg valacyclovir administered alone, and 80 mg of LY2140023 coadministered with 1000 mg valacyclovir) was included as a fixed

factor, and subject was a random factor. The parameters were log transformed before analysis. The least squares means (LSM) for each treatment and the 90% confidence intervals (CI) for the difference in means between test and reference treatment groups were estimated from the model and back transformed from the log scale to provide estimates of the geometric means and 90% CIs for the ratio of geometric means. The analysis of t_{max} was based on a nonparametric method. Medians and range for treatments and the P value computed for comparison of median values using Wilcoxon signed rank test are presented.

Safety. There were no serious adverse events (AEs) in this study. One subject discontinued from the study after experiencing a mild AE of urticaria that occurred approximately 4 hours after receiving 1000 mg of valacyclovir alone.

Most AEs were mild or moderate; one severe AE of headache occurred after valacyclovir alone. The most common AEs after prodrug alone were nausea, dizziness, somnolence, and headache. The AE profile for LY2140023 coadministered with valacyclovir was similar to LY2140023 alone.

Results

In Vitro Results

Validation of In Vitro System. The transport function of PEPT1 in transiently transfected HeLa cells was first assessed using extracellular pH of 6.0 and 7.5 to show that the uptake of the PEPT1 probe substrate [^{14}C]Gly-Sar was a proton-dependent process. The transport

Fig. 3. Concentration-dependent transport of LY2140023 in HeLa cells transiently transfected with PEPT1. The PEPT1-mediated transport of LY2140023 was observed over the concentration ranging from 5 to 146 μM . The nonspecific accumulation of LY2140023 was measured by conducting a parallel experiment in HeLa cells transfected with an empty vector, and values were subtracted from the PEPT1 transfected uptake. The reactions were incubated for 3 minutes at room temperature. Each symbol represents the PEPT1-mediated transport of LY2140023 after nonspecific accumulation adjustment.

TABLE 1

Concentration-dependent uptake of LY2140023 into HeLa cells to estimate kinetic parameters

The concentration dependent transport of LY2140023 was evaluated from either 5 to 146 (experiment 1) or 6.4 to 149 μM (experiment 2) LY2140023. All concentrations were performed in triplicate. The estimated K_m and $V_{\max}$ values represent parameter $\pm$ S.E.M.

Experiment	K_m μM	$V_{\max}$ pmol/min/mg
Experiment 1	28.66 ± 5.01	238.3 ± 20.8
Experiment 2	29.98 ± 5.29	572.8 ± 49.6

of [^{14}C]Gly-Sar at pH 6.0 was approximately five times higher than at pH 7.5 (Supplemental Fig. S1). Empty pcDNA3.1 vector-transfected cells (control cells) showed negligible passive permeability at both pH 6.0 and 7.5 (Supplemental Fig. S1). The transport kinetics of [^{14}C]Gly-Sar were assessed in the concentrations ranges from 50 μM to 5 mM to confirm the transport function of the in vitro system. Subsequently, the data were fitted in a model representing the uptake as a combination of passive diffusion and PEPT1-mediated transport. PEPT1-mediated transport of [^{14}C]Gly-Sar exhibited saturable kinetics with K_m and $V_{\max}$ values of 427.9 μM and 3975.3 pmol/min/mg, respectively (Supplemental Fig. S2), similar to reported K_m and $V_{\max}$ of 500 μM and 3517 pmol/min/mg in CHO cells transfected with PEPT1 (Han, 1999). The passive diffusion rate measured in control cells was 0.0972 $\mu\text{l/min/mg}$.

Inhibitory Effect of the Prodrug on PEPT1 [^{14}C]Gly-Sar Transport. The inhibitory effect of LY2140023 on the PEPT1 probe substrate [^{14}C]Gly-Sar (25 μM) was examined at concentrations ranging from 5 to 1000 μM . The accumulation of [^{14}C]Gly-Sar in the absence of LY2140023 was used as the positive control. The passive diffusion of [^{14}C]Gly-Sar at each concentration was measured by conducting parallel experiments in control cells transfected with a pcDNA3.1 empty vector and the values were subtracted from the accumulation in PEPT1-transfected HeLa cells. The estimated IC_{50} values of the prodrug in two separate experiments were 0.023 ± 0.09 and 0.013 ± 0.07 mM, respectively, with the mean value of 0.018 mM (Table 2).

Evaluation of Prodrug and Active Moiety Uptake by PEPT1. The uptake of amino-acid prodrug [^{14}C]LY2140023 (30 μM ; prodrug) or the active drug [^{14}C]LY404039 (30 μM ; active moiety) was conducted at pH 6.0 or 7.5 in HeLa cells transiently transfected with PEPT1 to determine if LY2140023 or LY404039 were substrates of PEPT1 (Fig. 2). The level of accumulation of the active moiety in HeLa cells transfected with PEPT1 was similar to its passive accumulation, indicating that it was not transported by PEPT1. In contrast, as illustrated

in Fig. 2, prodrug uptake was both a proton- and time-dependent process, suggesting that it was a PEPT1 substrate. Although the passive permeability of the prodrug, as indicated by uptake into the pcDNA3.1 empty vector, was slightly higher than that seen for the active moiety it is still negligible compared with the pH-dependent transport mediated by PEPT1.

As illustrated in Fig. 3, the transport of the prodrug was a concentration-dependent process that followed Michaelis-Menten saturation kinetics. The nonspecific accumulation of the prodrug at each concentration was measured by conducting parallel experiments in HeLa cells transiently transfected with an pcDNA3.1 empty vector. After subtraction of nonspecific accumulation, the PEPT1-mediated transport of the prodrug was fitted to Michaelis-Menten kinetic model to obtain K_m and $V_{\max}$ values (Table 1).

Determination of IC_{50} of known PEPT1 Inhibitors against the Prodrug. The inhibitory potentials of known PEPT1 substrates on [^{14}C]LY2140023 (prodrug) transport were determined using the dipeptide Gly-Sar as a positive control for inhibition of [^{14}C]LY2140023 uptake. The potential to inhibit 10 μM [^{14}C]LY2140023 uptake was determined for several known PEPT1 substrates; the range of mean IC_{50} values from two separate experiments on [^{14}C]LY2140023 uptake was between 0.46 and 25.90 mM (Table 2), with valacyclovir being the most potent and L-DOPA being the least potent inhibitor. A similar rank order of IC_{50} potency was observed for both [^{14}C]Gly-Sar and the prodrug, with the exception of cephalixin being a more potent inhibitor of prodrug uptake than captopril, whereas the reverse is true on the inhibition of Gly-Sar uptake (Table 2). The inhibitory potency of LY2140023 against Gly-Sar was more potent than any tested drugs.

Evaluation of Clinical Implication using In vitro data. To inform possible choices of inhibitors for a clinical study of PEPT1-mediated interactions, in vitro IC_{50} of five marketed drugs (cefadroxil, cephalixin, captopril, enalapril, and valacyclovir) were compared with their estimated concentrations in the gastrointestinal (GI) tract (I_2). These concentrations (I_2) were obtained by dividing the recommended clinical dose by a volume of 250 ml (volume of glass of water) (Table 3). The doses of compounds were obtained from Physicians' Desk Reference (1997). The ratios of I_2/IC_{50} were substantially less than one (i.e., the estimated GI concentrations were lower than the mean in vitro IC_{50} values) for captopril (0.03 to 0.15), cephalixin (0.18 to 0.37), and enalapril (0.008 to 0.03), but were greater than one (i.e., the estimated GI concentrations were greater than the in vitro IC_{50} values) for cefadroxil (2.10 to 4.20) and valacyclovir (12.04 to 24.11), indicating the potential for an interaction. The I_2/IC_{50} for LY2140023 using 80 mg dose was 48.5 greater than the ratios for valacyclovir.

Clinical Results

Demographics and Disposition. A total of 24 healthy subjects, 8 men and 16 women, with a mean age of 31.5 years (range 19 to 66 years of age) enrolled in this study. Twelve (50.0%) subjects were Caucasians, 11 (45.8%) were African American, and 1 (4.2%) was Asian. The mean body mass index was 26.6 kg/m².

Of the 24 subjects enrolled, 20 completed the study. The four subjects discontinued for the following reasons: failure to meet eligibility criteria (1 subject was discontinued before dosing), AE (1), and protocol violation. Twenty-three subjects received 1000 mg valacyclovir alone, 21 subjects received 80 mg of LY2140023 alone, and 20 subjects received valacyclovir coadministered with LY2140023.

Pharmacokinetics. After administration of the prodrug, the active moiety was formed rapidly and was present at the first sampling time in 18 of 21 subjects, which is consistent with previous clinical studies.

Mean PK parameters (Table 4) and profiles (Fig. 4A) were similar after dosing of LY2140023 (the prodrug) alone and when coadministered with valacyclovir. Ratios of LSM for *C*_{max} and AUC resulted in ratios that were close to 1 with confidence intervals contained within the 0.80 to 1.25 range (Table 5).

Similarly, the plasma PK parameters (Table 4) and profiles (Fig. 4B) for LY404039 (the active moiety) were similar after dosing of the prodrug alone and when coadministered with valacyclovir. Urinary excretion of the active moiety was also similar for the prodrug alone and with valacyclovir (Table 4), as measured by the fraction excreted (*f*_e; 0.651 and 0.595, respectively) and renal clearance (CL_r; 12.8 and 12.2 l/h, respectively). Ratios of LSM for *C*_{max} and AUC were also close to 1, and the CIs were contained within 0.80 and 1.25 (Table 5). The *t*_{max} analysis for prodrug and active moiety showed no significant differences observed for *t*_{max} (median of paired differences was 0.00 hour for prodrug and −0.07 hour for active moiety; Supplemental Table 1).

The valacyclovir plasma concentrations are limited and typically only measurable for 3 or 4 hours postdose (Phan et al., 2003), because conversion from valacyclovir (prodrug) to acyclovir (active metabolite) is rapid and efficient. Mean plasma profiles of valacyclovir were similar whether administered alone or with prodrug (Fig. 5A). As shown in Table 6, the valacyclovir plasma PK parameters and renal clearance were similar when administered alone or with the prodrug. Ratios of LSM for *C*_{max} and AUC were near 1 with CIs contained within the 0.80 to 1.25 range (Table 5), with the exception of the lower bound of the 90% CI for AUC(0–3), which was 0.71.

After administration of the prodrug valacyclovir, the active metabolite acyclovir was formed rapidly. The acyclovir plasma PK and renal clearance were similar when administered alone or with the prodrug (Table 6). Similarly, the plasma profiles for acyclovir were similar with or without administration of the prodrug (Fig. 5B). The ratios of LSM for AUC and *C*_{max} were close to 1, and the 90% CI were within the 0.80 to 1.25 range for acyclovir (Table 5). The *t*_{max} analysis for valacyclovir and acyclovir showed no differences observed for *t*_{max} (median of paired differences was 0.00 hour for valacyclovir and 0.00 hour for acyclovir; Supplemental Table 1).

Discussion

Despite broad substrate specificity, the potential for DDI at the PEPT1 transporter with new molecular entities (NMEs) has not been explored, because most of marketed PEPT1 substrates have low affinity for the transporter. However, the potential for an interaction cannot be ruled out when a drug or NME with a high inhibitory potential for PEPT1 is coadministered with a high-affinity substrate. Therefore, the current in vitro studies examined the DDI potential of LY2140023, a high-affinity substrate and a potent inhibitor of PEPT1, with PEPT1 substrates

TABLE 4

Geometric mean of pharmacokinetic parameters for LY2140023 and LY404039 after a single 80-mg dose of LY2140023 administered alone or with valacyclovir
Geometric mean (CV%) are presented for each parameter except where noted.

Treatment	LY2140023 Parameters		LY404039 Parameters

Fig. 4. Mean LY2140023 (A) and mean LY404039 (B) concentration-time profile after a single 80-mg dose of LY2140023 administered alone (●) or with valacyclovir (○).

and inhibitors using transiently transfected HeLa cells. HeLa cells do not possess any detectable endogenous peptide transport activity and thus are ideal for overexpression of the peptide transporters (Sugawara et al., 2000). These in vitro results were then used to guide the design of the clinical drug-drug interaction study with valacyclovir.

As determined in this study, the uptake of LY2140023 (prodrug) was shown to be a PEPT1-mediated, proton-dependent process, whereas LY404039 (the active moiety) was not transported by PEPT1 and did not show proton dependency. The PEPT1-mediated uptake of prodrug was further confirmed in Pept1 knockout mice. In the Pept1 knockout mice, the exposure as in $AUC_{0-\infty}$ and C_{max} of the prodrug were only 10% of the exposure in the wildtype mice (data on file, Eli Lilly and Company). In addition, the passive diffusion of the active moiety was comparable in PEPT1 and pcDNA3.1 empty vector transfected cells, indicating low passive diffusion of this compound. The passive diffusion for the prodrug was also low, and its uptake into the PEPT1-transfected cells was primarily mediated by the transporter and not by passive diffusion, indicating the prodrug enters into cells mainly through an active uptake process. The low passive permeability of the prodrug and active moiety were confirmed in MDCK-MDR1 cells. In the MDCK-MDR1 cells, the passive permeability of the prodrug and active moiety were

approximately 1×10^{-6} cm/s, which is lower than the low permeability marker atenolol (2.2×10^{-6} cm/s, data on file, Eli Lilly and Company) in this model. The MDCK cells have not shown to express PEPT1 (Quan et al., 2012), therefore the permeability represents their passive permeability across the monolayer. Taken together, the data clearly demonstrate that PEPT1 is responsible for the transport of the prodrug.

The inhibitory potential of LY2140023 was substantially more potent than any of the marketed drugs tested. As illustrated in Table 2, IC_{50} values of tested drugs against [^{14}C]Gly-Sar ranged from 0.74 to 14.9 mM, whereas IC_{50} value for LY2140023 was 0.018 mM. Similarly, the affinity of the prodrug was substantially higher than the PEPT1 probe substrate Gly-Sar. The estimated K_m values of the prodrug in two separate experiments were 28.66 and 29.98 μ M, respectively (Table 1), whereas the estimated K_m value for Gly-Sar was 427.9 μ M (Supplemental Fig. S2).

A variety of structurally diverse, marketed drugs that are PEPT1 substrates with different affinity for the transporter (for review of PEPT1 substrates with different affinity, see Brandsch et al., 2008) were evaluated for their inhibitory potencies against the prodrug. The rank order of IC_{50} values of the tested drugs against the prodrug were similar

to the rank order of IC_{50} values against Gly-Sar, indicating valacyclovir as the most and L-DOPA as the least potent inhibitor of PEPT1-mediated transport of the prodrug (Table 2). The possible clinical implication of PEPT1-mediated interactions was evaluated using the prodrug and a few well-characterized drug substrates of PEPT1: captopril, cefadroxil, cephalixin, enalapril, and valacyclovir. Subsequently, to normalize the inhibitory potential to the clinical dose, the in vitro IC_{50} values were divided by 250 ml (the volume of a glass of water). This is adapted from the transporter guidelines published by the US Food and Drug Administration (<http://www.fda.gov/downloads/drugs/guidancecomplianceregulatoryinformation/guidances/ucm292362.pdf>), European Medicines Agency (http://www.ema.europa.eu/docs/en_GB/document_library/Scientific_guideline/2012/07/WC500129606.pdf), and the International Transport Consortium (Giacomini et al., 2010) for P-glycoprotein and BCRP intestinal interaction. The guidelines suggest that the in vitro IC_{50} values for drugs be compared with the estimated concentrations in the gastrointestinal (GI) tract (I_2), which were obtained by dividing the recommended clinical dose by a volume of 250 ml (volume of a glass of water). The guidelines recommend conducting an in vivo DDI study when I_2/IC_{50} is greater than 10 (Giacomini et al., 2010; <http://www.fda.gov/downloads/drugs/guidancecomplianceregulatoryinformation/guidances/ucm292362.pdf>; http://www.ema.europa.eu/docs/en_GB/document_library/Scientific_guideline/2012/07/

WC500129606.pdf). For this study, because there is no prior experience to define a cut off value for the ratio, the inhibitor that gave the greatest I_2/IC_{50} ratio was chosen for the clinical study. Table 3 shows that the ratios of I_2/IC_{50} were substantially less than 10 (i.e., estimated GI concentrations were lower than the in vitro IC_{50} values) for captopril, cephalixin, and enalapril, between 1 and 10 for cefadroxil, and greater than 10 for valacyclovir, suggesting the highest potential for clinical interaction for valacyclovir. The ratio for LY2140023 was close to 50, indicating potential for interaction for the prodrug following the guidelines.

Subsequently, a clinical study was designed to evaluate LY2140023 as both a substrate and an inhibitor of PEPT1. The coadministration of LY2140023 and valacyclovir did not affect the PK of each other or their respective active moieties (LY404039 or acyclovir), indicating no clinical DDI between the prodrug and valacyclovir. The data also showed that the presence of the prodrug or valacyclovir did not affect the conversion of prodrug to its active moiety for either LY2140023 or for valacyclovir. The lack of interaction on the conversion of the prodrug and valacyclovir to its corresponding active moieties was expected, because different enzymes are responsible for their activation. Dehydropeptidase 1 has been shown to cleave the prodrug to its active moiety (Moulton et al., 2015) and valacyclovirase (biphenyl hydrolase-like protein) to cleave valacyclovir to acyclovir (Marsillach et al., 2014). For

both active moieties there was no change in the CL/F or the CL_r, indicating that coadministration of the drugs did not affect the renal clearance of each other. Furthermore, if there is a weak interaction at PEPT1, a shift in T_{max} values may be observed. However, no shift in T_{max} was observed for any of the entities studied. Also, for valacyclovir there was no significant change in the AUC(0–3 hours), again indicating no interaction at PEPT1.

In this study, we illustrated how in vitro studies can guide the design of clinical DDI studies for transporter-based interactions. In vitro screening of inhibitory potencies of multiple drugs that compete at the transporter could give the rank order of inhibitory potencies and an analysis for potential for DDI in relation to oral dose of the compound. Therefore, unnecessary in vivo studies could be avoided, while focusing on the most relevant potential for DDI. Although the in vitro study indicated the potential for a DDI between the prodrug and valacyclovir according to guideline for other intestinal transporters, an in vivo DDI study showed no interaction of these two drugs via PEPT1. Therefore, our results clearly illustrated that a clinical DDI at PEPT1 is highly unlikely even with a NME with high affinity for the transporter.

Authorship Contributions:

Participated in research design: Pak, Annes, Witcher, Knadler, Ayan-Oshodi, Mitchell, Leese, Hillgren.

Conducted experiments: Pak, Annes.

Performed data analysis: Pak, Long, Annes, Witcher, Ayan-Oshodi, Leese.

Wrote or contributed to the writing of the manuscript: Pak, Long, Witcher, Knadler, Ayan-Oshodi, Mitchell, Leese, Hillgren.
