CRISPR/Cas9 Genetic Modification of CYP3A5 *3 in HuH-7 Human Hepatocyte Cell Line Leads to Cell Lines with Increased Midazolam and Tacrolimus Metabolism

Molecular Epidemiology Laboratory, Minneapolis Medical Research Foundation, Minneapolis, Minnesota

Received April 13, 2017; accepted May 18, 2017

ABSTRACT

Clustered regularly interspaced short palindromic repeats (CRISPR)/Cas9 engineering of the CYP3A5 *3 locus (rs776746) in human liver cell line HuH-7 (CYP3A5 *3/*3) has led to three CYP3A5 *1 cell lines by deletion of the exon 3B splice junction or point mutation. Cell lines CYP3A5 *1/*3 sd (single deletion), CYP3A5 *1/*1 dd (double deletion), or CYP3A5 *1/*3 pm (point mutation) expressed the CYP3A5 *1 mRNA and had elevated CYP3A5 mRNA (P < 0.0005 for all engineered cell lines) and protein expression compared with HuH-7. In metabolism assays, HuH-7 had less tacrolimus (all P < 0.05) or midazolam (MDZ) (all P < 0.005) disappearance than all engineered cell lines. HuH-7 had less 1-OH MDZ (all P < 0.0005) or 4-OH (all P < 0.005) production in metabolism assays than all bioengineered cell lines. We confirmed CYP3A5 metabolic activity with the CYP3A4 selective inhibitor CYP3CIDE. This is the first report of genomic CYP3A5 bioengineering in human cell lines with drug metabolism analysis.

Introduction

More than 50% of the oral drugs in the United States are enzymatically metabolized by the cytochrome P450 (P450) family of enzymes (Guengerich, 2008). The P450s and other drug-metabolizing enzymes are polymorphic, resulting in large variability in metabolic clearance of drugs. In vitro systems to study drug metabolism and genetic variation include cloned and expressed enzymes, human and animal microsomes from individual or pooled donors, and freshly isolated and cultured or cryopreserved hepatocytes; however, primary hepatocytes are not an optimal option because they require harvesting liver, they are expensive, they are not immortalized, and they are highly variable from specimen to specimen. To study genetic variants’ association with metabolism, a genomically heterogeneous and from uncontrolled environments, whereas cell line models are, for the most part, genomically identical except for any specifically altered genetic variant. Thus, we developed genomically heterogeneous and from uncontrolled environments, whereas cell line models are, for the most part, genomically identical except for any specifically altered genetic variant. Thus, we developed

ABBREVIATIONS: bp, base pair; CRISPR, clustered regularly interspaced short palindromic repeats; dd, double deletion; gRNA, guide RNA; HDR, homology directed repair; MDZ, midazolam; NHEJ, nonhomologous end joining; 1-OH MDZ, 1-hydroxy midazolam; 4-OH MDZ, 4- hydroxyl midazolam; pm, point mutation, P450, cytochrome P450; PAM, proto-spacer adjacent motif, PCR, polymerase chain reaction; sd, single deletion; SNP, single nucleotide polymorphism; Tac, tacrolimus.
and CYP3A5 (Pelkonen et al., 2008; Tseng et al., 2014). Consequently, the CYP3A5 genotype is an important factor in determining the appropriate doses of drugs. People of African ancestry are often underdosed initially with Tac after organ transplantation (Jacobson et al., 2011), in part owing to the high prevalence of the CYP3A5*1 allele in the African American population (allele frequency, 0.85). Carriers of the CYP3A5*1 allele often need higher doses of drugs that are CYP3A5 substrates to achieve therapeutic drug levels in the blood. Therefore, there is a need to develop an in vitro, cell culture–based system to understand the effects of genetic variants on drug metabolism before the clinical use of new drugs or to improve dosing of existing drugs.

The first step in development of a suitable liver cell line was to find a clinically relevant parental cell line. To date, there is no commercially available liver cell line that is diploid at chromosome 7 and expresses CYP3A5*1. The Caco-2 cell line (Sambuy et al., 2005) is a human intestinal cell line that metabolizes drugs, but it has five copies of chromosome 7 and thus is not suitable for studying the diploid CYP3A5 seen in most patients. The HuH-7 cell line (Nakabayashi et al., 1984, 1985) was derived from a heptic carcinoma that can convert the substrate MDZ, primarily through CYP3A4 activity, in cell culture to its metabolite products hydroxylated 1-OH MDZ and 4-OH MDZ (Choi et al., 2009; Sivertsson et al., 2010, 2013); however, HuH-7 cells are not very efficient at MDZ metabolism because they are homozygous for the slow metabolizing CYP3A5*3 allele. Thus, there is a need to develop a liver cell line that mimics the rapid drug metabolism associated with the CYP3A5*1 genotype in cell culture.

We hypothesized that by genetically modifying the HuH-7 cell line to the more metabolically active CYP3A5*1/*1 or *1/*3 genotypes, the cells would have increased MDZ and Tac metabolic activity. To test the hypothesis, we used CRISPR/Cas9 bioengineering (Mali et al., 2013c; Ran et al., 2013) to develop and characterize new cell lines and then phenotypically evaluate the genotypes’ effects on MDZ and Tac metabolism. These newly engineered cells can be used as a parental cell line in future studies to assess the association of additional genetic variants with drug metabolism and metabolism of other drugs. This is the first report of genomic CYP3A5 bioengineering in human cell lines and functional analysis of associated drug metabolism phenotypes.

### Materials and Methods

#### Selection of HuH-7 Hepatocyte Cell Line as Parental Cell Line

We selected HuH-7, liver carcinoma cells from the Japanese Cell Research Bank (catalog no. JCRB0403) because 1) HuH-7 cells metabolized MDZ in cell culture (Sivertsson et al., 2010, 2013); 2) HuH-7 cells were diploid, at chromosome 7, where both CYP3A4 and CYP3A5 are located, and therefore are clinically relevant; 3) we sequenced the cells at the CYP3A5*3, *6, and *7 loci, and HuH-7 cells carried *3/*3 alleles at the rs776746 locus, a defined variant to change via CRISPR/Cas9 bioengineering to the more functional *1/*1 allele; 4) these HuH-7 cells were also *1/*1 at the loss of function CYP3A4*22 (rs5599367) allele; 5) we confirmed CYP3A4 and CYP3A5 mRNA expression by quantitative reverse transcription-polymerase chain reaction (PCR).

#### Parental Cell Line Characterization

HuH-7 (Nakabayashi et al., 1984, 1985), hepatoma cells from a 57-year-old Japanese man, were purchased from the Japanese Cell Research Bank (Osaka, Japan) and used as parental cell line for genetic modification. Cells were grown in Dulbecco’s modified Eagle’s medium (DMEM) with high glucose and pyruvate supplemented with 10% fetal bovine serum and antibiotic-antimycotic (Gibco, Carlsbad, CA), which we refer to as “media” throughout the rest of this article.

#### Genotyping of Cell Lines

Genomic DNA was isolated from HuH-7 cells using the Roche High-Pure PCR template preparation kit. PCR and sequencing primers (Supplemental Table 1) surrounding single nucleoside polymorphisms (SNPs) CYP3A4*22 (rs5599367, C>T), CYP3A5*3 (rs776746, 4968A> G), *6 (rs10264272, 14690G> A), and *7 (rs41303343, nonfunctional) were designed using the NCBI primer-BLAST primer design tool. The sequences surrounding the SNPs in the genomic DNA from the HuH-7 cells were PCR-amplified using AccuPrime PfX DNA polymerase kit (Thermo Fisher, Somerset, NJ), and then the PCR products were characterized on 1% agarose gel or purified with the Qiagen (Hilden, Germany) PCR clean-up kit and sequenced. PCR products were then Sanger-sequenced using the primers listed in Supplemental Table 1 by University of Minnesota Genomics Center.

#### Plasmids Guide RNA Construction and Transfection

A plasmid that expressed a human codon-optimized Cas9 (Mali et al., 2013a) nuclease was purchased from Addgene (Cambridge, MA) guide RNAs (gRNAs) targeting the CYP3A5*3 locus were designed using the CRISPR design tool (http://crispr.mit.edu). DNA gBLOCKs were designed, synthesized, and purchased from Integrated DNA Technologies (Haliaix, NS) combining the gRNA from the CRISPR design tool with the gRNA synthesis protocol (Mali et al., 2013a) from Addgene. The gBLOCKs were TOPO-cloned using the Zero Blunt TOPO PCR cloning kit into pCRBlunt II-TOPO vector (Thermo Fisher Scientific). Plasmids were expanded in One Shot StarL chemically competent Escherichia coli bacteria purchased from Thermo Fisher. Plasmids were sequence-verified.

Plasmids were then prepared for transfection according to the Qiagen Plasmid Maxi kit. Plasmids were quantified and assessed for purity using a NanoDrop 2000 UV/Vis spectrophotometer. Newly designed gRNAs and hCas9 plasmid DNA were transfected into the HuH-7 cells using a Neon Transfection System (Thermo Fisher).

#### Surveyor Assay to Select Guide RNAs

Genomic DNA was isolated from transfected cells, and then we performed Surveyor assay to screen gRNAs for ability to cut at CYP3A5*3 locus using a modified protocol (Guschin et al., 2010) along with Surveyor enzyme from Surveyor Mutation Detection kit for standard gel electrophoresis from Integrated DNA Technologies. Briefly, DNA was extracted from bulk transfected cells using Roche High-Pure PCR template preparation kit. PCR was performed using AccuPrime Taq DNA polymerase, high-fidelity with CYP3A5 specific primers Cel1F*3 (5’-CAACTCCGGCTTCAAGCTG-3’) and Cel1R*3 (5’- ACCAGAGAGACGAGACTTCTTT-3’) to produce a 397-base-pair (bp) product (if no deletions). Bio-Rad (Hercules, CA) thermocycler was programmed as follows: 1) 94°C for 5 minutes; 2) 94°C for 15 seconds; 3) 56°C for 30 seconds; 4) 68°C for 0.5 minutes; 5) step 2, repeated 34 times; 6) 68°C for 0.5 minutes; and 7) 4°C indefinitely. PCR products were denatured and reannealed after a published protocol (Guschin et al., 2010) and visualized in a 10% Bio-Rad Criterion TBE gel to determine DNA heteroduplexes from heterogenous cell cultures caused by CRISPR/Cas9 and gRNA targeting (Supplemental Fig. 3).

#### Transfection with Selected gRNA and hCAS9

To create cell lines that delete the CYP3A5*3 splice junction, via nonhomologous end joining (NHEJ), two selected gRNAs (gRNA1 and gRNA2) and hCas9 plasmids were transfected into the HuH-7 cells using the Neon transfection system. The two gRNAs target each side of the CYP3A5*3 locus. The resultant cells were then single-cell–cloned to produce homogenous cell lines.

To create the point mutation (pm) cell line, gRNA2 was transfected into cells, with a homology-directed repair (HDR) template (HDR single-stranded DNA template ssODN 3A5*3-E3). The sequence of ssODN 3A5*3-E3 is 5’- gcctaaagatgaatctactattatgaataaataatctttcttgatttcgaataacctttccatccatcatatgagacgagtgtgggcttcc-3’. The underlined g indicates the 2b base that is changed from a guanine (g). The lowercase letters are the intron sequence, and the upper-case letters are the exon 3B sequence. The cells were treated with 1 μM SCR7 (Xcessbio, San Diego, CA) and 5 μM L7,55,507 (Xcessbio) at the time of transfection and for 7 days after transfection until single-cell cloning.

#### Single-Cell Cloning and Cell Line Screening via PCR and DNA Sanger Sequencing

Transfected cells were plated in media/soft agar mixture as previously described (Kim et al., 2014; Dorr et al., 2015) and propagated to become a homogeneous cell line. Specifically, in 150 mm 15 ml of a 0.6% solution of Ultralow melting-point agarose (Thermo Fisher Scientific, catalog no. 16520-100) in media was plated at 38.5°C and cooled until solid. Next, 15,000 transfected cells in 15 ml of 38.5°C media with 0.3% Ultralow melting-point agarose was layered on top and cooled. The plate was covered with 10 ml of media and incubated at 37°C with 5% CO2 for about 3–5 weeks until cell colonies were visible. Colonies were then picked with a sterile 200-μl pipette tip and transferred to individual wells of a 96-well collagen I-coated plate and cultured until confluent (approximately 3 to 4 weeks).
For large-scale screening, we dissociated the cells using trypsin-EDTA (0.25%) and transferred half the culture to fresh 96-well plates with media and grown. The remaining cells in the 96-well plate were centrifuged at 350g for 5 minutes. Trypsin was removed, and the cell pellets were lysed using the QuickExtract DNA extraction solution from Epizentech Biotechnology (Madison, WI). Lysates were used as a PCR template and then PCR-amplified using an AccuPrime Pfx DNA polymerase kit in 96-well PCR plates. The primers for amplification of the CYP3A5 region were designed using NCBI primer design (http://www.ncbi.nlm.nih.gov/tools/primer-blast/) and are 7853F (5′-GCATT-TAGGCTGTGAGCACCTTG-3′) and 8030R (5′-CATACGTCTTGGTG-GGGACAAC-3′). Thermocycler was programmed as follows: 1) 94°C for 5 minutes; 2) 94°C for 15 seconds; 3) 55°C for 30 seconds; 4) 68°C for 30 seconds; 5) gap to step 2, 34 times; 6) 68°C for 7 minutes; 7) 4°C indefinitely. PCR products were purified using the MiniElute 96 UF PCR purification kit (Qiagen), characterized by electrophoresis through a 2% agarose gel, and sequenced by the following PCR products. Sequencing was performed by the University of Minnesota Genomics Center using sequencing primer 7884F (5′-ACCTGGCCTCATAATTTACTG-3′) and 8267R (5′-CTTCACTAGCGATGACTTCG-3′). Sequence data were analyzed using DNA Star Lasergene and Geneious software.

RNA Splicing Assay. RNA was isolated from the confluent cells using the Qiagen RNasey Mini Kit. RNA was quantified using the Qubit 2.0 fluorometer and the Qubit RNA BR Assay Kit. RNA was then converted to cDNA using oligo-dT primer and ThermoScript Reverse Transcriptase kit. CYP3A5 *1/*3 or *1/*1 heterozygous human liver RNA was also used as controls and cDNA made by the same method. PCR primers were developed using the NCBI primer design tool and mRNA sequence file of CYP3A5 (Genbank accession no. BC025176.1) of the 500 bp surrounding the *3 nucleotide locus. The cDNA was then used as PCR template with the following primers: CYP3A5 cDNA ex2F (5′-GTCACAATCTGCTGAATGCATG-3′) and CYP3A5 cDNA ex5R (5′-TGAGGACGACGATGCGT-3′). Thermocycler settings were as follows: 1) 94°C for 5 minutes; 2) 94°C for 15 seconds; 3) 55°C for 30 seconds; 4) 68°C for 30 seconds; 5) step 2, repeated 34 times; 6) 68°C for 5 minutes; 7) 4°C forever using the AccuPrime Pfx DNA polymerase kit. PCR products were purified using the QiaQuick PCR purification kit; characterized by electrophoresis through a 2% agarose gel and imaged using ethidium bromide staining and a Bio-Rad gel documentation system.

Quantitative RT-PCR to Detect CYP3A5 Transcripts. CYP3A5 mRNA was quantified using cells from the MDZ and Tac assays. The primers were the same as for the mRNA splicing assay (Supplemental Table 1). The RNA was the same as the mRNA splicing assays, and GAPDH primers were used as the reference control; 2 μg of RNA was converted to cDNA, and 5 μl of 1 in 20 diluted cDNA was used in a 20-μl reaction mix for SYBR Green assay-based quantitative RT-PCR. We used a Roche (Basel, Switzerland) light cycler and made graphs using the AccuPrime Pfx DNA polymerase kit in 96-well PCR plates. The primers for amplification of the CYP3A5 region were designed using NCBI primer design (http://www.ncbi.nlm.nih.gov/tools/primer-blast/) and are 7853F (5′-GCATT-TAGGCTGTGAGCACCTTG-3′) and 8030R (5′-CATACGTCTTGGTG-GGGACAAC-3′). Thermocycler was programmed as follows: 1) 94°C for 5 minutes; 2) 94°C for 15 seconds; 3) 55°C for 30 seconds; 4) 68°C for 30 seconds; 5) gap to step 2, 34 times; 6) 68°C for 7 minutes; 7) 4°C indefinitely. PCR products were purified using the MiniElute 96 UF PCR purification kit (Qiagen), characterized by electrophoresis through a 2% agarose gel and sequenced by the following PCR products. Sequencing was performed by the University of Minnesota Genomics Center using sequencing primer 7884F (5′-ACCTGGCCTCATAATTTACTG-3′) and 8267R (5′-CTTCACTAGCGATGACTTCG-3′). Sequence data were analyzed using DNA Star Lasergene and Geneious software. All comparisons were conducted using t test for continuous variables.

**Results**

Genotyping of Single-Cell Clones after CRISPR/Cas9 Bioengineering of CYP3A5. To create CYP3A5 *1 cells from the HuH-7 cells that were CYP3A3, we altered CYP3A5 based on CRISPR proto-spacer adjacent motifs (PAM) near the exon 3B splice junction (Fig. 1). To identify the cell line that had the exon 3B splice junction deleted, we screened single-cell clones by PCR amplification, then forward and reverse Sanger sequencing of a 451-bp region flanking the splice junction (Fig. 1). The splice junction contains the 3′ locus (rs776746), and we deleted this junction to express CYP3A5 *1 mRNA via alternative splicing. These cells were transfected with gRNA1, gRNA2, and hCas9 plasmids (Fig. 2). We screened 235 single-cell clones, and 74 (32%) were mutated. Mutations in modified cell lines were as follows: 22 (9.4%) had heterozygous frameshift near one of the two gRNA cut sites, 23 (9.8%) were heterozygous for the 77-bp deletion between gRNA sites, 15 (6.4%) cell lines were homozygous for the 77-bp deletion, and 14 (6.0%) cell lines were classified as “other.” The “other” mutations in cell lines include cell lines that had multiple
frameshifts or were heterozygous for a deletion and frameshift or had other mutations. The heterozygous deletion cell line was designated CYP3A5 *1/*3 sd (sd = single deletion), and the homozygous deletion cell line was designated CYP3A5 *1/*1 dd (Fig. 3).

To identify the cell line CYP3A5 *1/*3 pm (pm = point mutation) (Fig. 3), we screened 212 single-cell clones using DNA sequencing that were transfected with hCAS9, gRNA2 and HDR template (Fig. 2); 33 (16%) were mutated. Mutations in cell lines were as follows: 23 (11%) had a heterozygous frameshift near the gRNA2 cut site, 2 (0.9%) had homozygous frameshift, 1 (0.5%) had heterozygous point mutation at *3 locus, 0 (0.0%) had homozygous point mutations at *3 locus, and 8 (4.0%) were classified as "other." These other mutants include cell lines that had multiple frameshifts, were heterozygous for a deletion and frameshift, or had other mutations.

**PCR Characterization of Genomic DNA in New Cell Lines.** Of the cell lines that were sequenced, select cell lines that were CYP3A5 *1/*3 or *1/*1 by Sanger sequencing were validating by PCR characterization of genomic DNA at the CYP3A5 *3 locus (Fig. 4, A and B). The 77-bp deletions were characterized by PCR amplification of genomic DNA and visualized by 2% agarose gel electrophoresis (Fig. 4B). Both heterozygous (CYP3A5 *1/*3 sd) and homozygous (CYP3A5 *1/*1 dd) cell lines were developed with the 77 bp CYP3A5 exon 3B’ splice junction deleted. The point mutation heterozygous cell line, CYP3A5 *1/*3 pm, did not have a deletion at the splice junction (Fig. 4B). These cell lines were then further validated with Sanger sequencing (Supplemental Fig. 1).

CYP3A5 mRNA Splicing Assay and Sequencing of Engineered Cells. CYP3A5 mRNA splice variants were evaluated by gel electrophoresis at the *3 locus to ensure that the deletion, or point mutation, of the CYP3A5 exon 3B’ splice junction changed the cells to express the *1 mRNA instead of the *3 mRNA (Fig. 5, A and B). Keuhl et al. (2001) have previously shown that the 131-bp exon 3B was present in the CYP3A5 *3 mRNA and absent in the *1 mRNA, which was confirmed by Busi and Cresteil (2005a, b). Total mRNA from the cell lines was converted to cDNA and then PCR-amplified with primers that flanked the CYP3A5 exon 3B to determine whether the exon 3B was absent in the engineered cell lines. RNA from human liver cDNA genotyped as *1/*3 was used as the control (Fig. 5B). This mRNA splicing assay confirmed the absence of the *3 mRNA in the newly developed cell line, CYP3A5 *1/*1 dd. Additionally, the *1/*3 heterozygote cell lines, CYP3A5 *1/*3 sd and CYP3A5 *1/*3 pm, expressed both the *1 and the *3 mRNA splice variants as compared with the human liver cDNA controls (Fig. 5B). To further validate the identity of the CYP3A5 splice variants in the cell lines, we sequenced the CYP3A5 mRNA via Sanger sequencing of the CYP3A5 RT-PCR products (Supplemental Fig. 2). The sequences confirmed that the exon 3B was absent in the CYP3A5 *1/*1 dd cell line when aligned to a *3 sequence. The CYP3A5 *1/*3 pm sequences became jumbled at exon 3B, as expected when sequencing a heterozygote (Supplemental Fig. 2); however, sequencing in forward and reverse directions confirmed that the CYP3A5 *1/*3 heterozygote-engineered cells expressed both the CYP3A5 *3 and *1 mRNAs.

**Quantitative RT-PCR Resulted in Elevated CYP3A5 Transcripts in *1 Expressing Cell Lines.** Quantitative RT-PCR showed significantly elevated CYP3A5 mRNA expression in CYP3A5 *1/*1 dd compared with HuH-7 CYP3A5 *3/*3 cells ($P = 2.5 \times 10^{-6}$). All engineered
**CYP3A5 *1** cell lines had elevated CYP3A5 mRNA expression compared with HuH-7 (P ≤ 0.0001) (Fig. 5C). The CYP3A5 *3* mRNA, expressed in cell lines, was targeted for nonsense-mediated decay as the likely cause of reduced CYP3A5 mRNA in *3* cell lines. The CYP3A5 *1/*3* cell lines had intermediate CYP3A5 mRNA expression compared with HuH-7 CYP3A5 *1/*3* and CYP3A5 *1/*1* dd (Fig. 5C).

**Immunoblot Confirms for CYP3A5 Expression in Engineered Cell Lines.** We immunoblotted for the CYP3A5 protein expression in the cell lines using two separate primary antibodies: KO3 (Schuetz et al., 1996), which detects CYP3A family (including CYP3A4 and CYP3A5), or the CYP3A5-specific WB-3A5 (Schmidt et al., 2004) (Fig. 6). The CYP3A5 *1/*3* sd cell line visually expressed less CYP3A5 protein expression than CYP3A5 *1/*1* dd but higher expression than the CYP3A5 *3/*3* HuH-7 cells. The CYP3A5 *1/*3* pm cell line had poor CYP3A5 protein expression compared with the CYP3A5 *1/*3* sd cell line (Fig. 6). These results were consistent with both the KO3 and WB-3A5 antibodies. It is likely that the K03 antibody did not detect much CYP3A4 protein owing to low CYP3A4 expression in the HuH-7 cell line. Thus, the bioengineered cell lines express CYP3A5 protein.

**Metabolism Assays Show CYP3A5 *1* Expressing Cells Have Increased MDZ and Tac Metabolism Compared with CYP3A5 *3/*3* HuH-7 Cells.** As shown in Fig. 7A, we performed an MDZ metabolism assay to determine whether the new cell lines metabolized MDZ to the products 1-OH MDZ and 4-OH MDZ. We also quantitated Tac disappearance using the metabolism assay. As expected, the CYP3A5 *3/*3* (HuH-7) cells had higher levels of Tac (Fig. 7B) and MDZ (Fig. 7C) in cell culture after overnight incubations than CYP3A5 *1/*3* sd, CYP3A5 *1/*3* pm, or CYP3A5 *1/*1* dd cell lines because of the decreased metabolism by the CYP3A5 *3/*3* cells. Furthermore, increased production of 1-OH MDZ (Fig. 7D) and 4-OH MDZ (Fig. 7E) was observed by the engineered cell lines compared with the parental HuH-7 cell line. Significant metabolic differences between each of the cell lines were found by comparing substrate disappearance or product formation between the engineered cell lines and the Hu-H7 parental cell line (all P < 0.05) (Table 1). Thus, the engineered CYP3A5 *1*-expressing cell lines were more efficient at converting MDZ to its hydroxylated metabolites compared with the CYP3A5 *3/*3* parental HuH-7 cell line. The engineered CYP3A5 expressing cells are also more active at metabolizing Tac than the Hu-H7 cells, which coincides with previous studies with cloned, expressed CYP3A4 and CYP3A5 that demonstrated that the intrinsic clearance of Tac is higher for CYP3A5 than CYP3A4 (Dai et al., 2006).

**CYP3CIDE as a Selective CYP3A4 Inhibitor in MDZ Assays.** CYP3CIDE (Walsky et al., 2012; Tseng et al., 2014) is a selective inhibitor of CYP3A4 that can also inhibit CYP3A5 at higher concentrations. The concentration-dependent effects of CYP3CIDE are shown in Fig. 8A. To determine the concentration of CYP3CIDE to use in cell culture, we did a dose-response study with the HuH-7 (CYP3A5 *3/*3*) and CYP3A5 *1/*1* dd cell lines (Fig. 8B). After the dose-response study, the cell lines were incubated with MDZ with or without 50 μM CYP3CIDE to assess CYP3A4 activity in modified cell lines. When CYP3CIDE was present, there was slight difference in the MDZ reduction by the HuH-7 cell line (P = 0.044). The MDZ reduction was more pronounced in all the CYP3A5 *1*-expressing cell lines comparing those with and those without CYP3CIDE (P ≤ 0.005) (Fig. 9A). The 1-OH MDZ production by HuH-7 cells was lower with CYP3CIDE (P < 0.05), whereas all three CYP3A5 *1*-expressing cell lines had even more significant reduction of 1-OH MDZ production (all P ≤ 0.005) (Fig. 9B). Further analysis of MDZ metabolism by the cell lines with 4-OH MDZ as the minor metabolic product (Fig. 9C) showed that CYP3CIDE almost completely halted 4-OH MDZ production by...
HuH-7 cells \( (P = 0.007) \). Figure 9C also showed that HuH-7 and CYP3A5 *1/*3 sd cell lines had less 4-OH MDZ production with CYP3CIDE \( (P \leq 0.01 \) and \( P \leq 0.05 \), respectively). Neither CYP3A5 *1/*1 dd nor CYP3A5 *1/*3 pm had significant 4-OH MDZ production differences with CYP3CIDE \( (P > 0.05) \). These CYP3CIDE experiments showed that these cell lines had differential activity when a selective CYP3A4 inhibitor was present, indicating phenotypically active CYP3A5, which was not present in the parental HuH-7 \( (CYP3A5 *3/*3) \) cell line.

**Discussion**

This study showed the successful CRISPR/Cas9 bioengineering of a human liver cell line, HuH-7, to create new cell lines that express the common CYP3A5 *1 variant that is known to be highly relevant toward drug metabolism. Unlike recent reports using CRISPR/Cas9 to knock out CYP2E1 (Wang et al., 2016) or CYP3A1/2 (Lu et al., 2017) function in rats, we used CRISPR/Cas9 to activate CYP3A5 expression in human cell lines by conversion of *3 to *1 genotype. This is the first report of engineered cell lines for both heterozygous and homozygous CYP3A5 *1 expression in human liver cell culture and phenotypic analysis.

This study showed that it is possible to use two methods of CRISPR/Cas9 biotechnology to modify the HuH-7 cells to express CYP3A5 *1 by splice junction deletion using two gRNAs or with one gRNA and a homology-directed repair template. Without the need for fluorescent-activated cell sorting or less precise limiting dilution techniques, a soft agar clonal selection with expansion on collagen I–coated plates technique was used to isolate unique human hepatocyte cell lines. This technique is important in isolating hepatocyte cell lines because the cells do not grow well as single cells on standard plastic cell culture dishes. Also, growing the cell lines at confluence for 2 to 3 weeks, layering with Matrigel (Corning), and inducing the cells with rifampicin and phenytoin increased the hepatocytes’ metabolic activity. We determined the impact of induction while developing the MDZ

**Fig. 6.** Characterization of **CYP3A5** protein expression in genetically modified cell lines. Immunoblot with primary (1°) antibodies KO3 antibody (Schuetz et al., 1996) that recognizes P450 family proteins, including CYP3A4 and CY3A5, and WB-3A5 (Schmidt et al., 2004), which is specific for CYP3A5 or β-actin as a reference.

**Fig. 7.** MDZ and Tac metabolism assays confirm that CYP3A5 *1–expressing cells have increased metabolic activity compared with HuH-7 CYP3A5 *3/*3–expressing cells. (A) Metabolism assay used in this study. Cells were plated on collagen I–coated plates and grown at confluence for 2 to 3 weeks and then layered with Matrigel. Cells were then induced with rifampicin and phenytoin for 3 days; then a substrate of Tac or MDZ was added overnight. Cell culture media were collected and assayed for Tac, MDZ, or the MDZ products 1-OH MDZ or 4-OH MDZ by liquid chromatography-mass spectrometry. (B) Tac was used as the substrate and was assayed to assess its disappearance. Each column represents five biologic replicates of a representative experiment and shows the disappearance of the Tac caused by the cells’ metabolism. (C) MDZ was used as the substrate to assess its metabolism. Each column represents six biologic replicates of a representative experiment and shows the disappearance of the MDZ caused by the cells’ metabolism. (D) The corresponding 1-OH MDZ products from the MDZ experiments and the (E) corresponding 4-OH MDZ products.
CRISPR Modification of CYP3A5 in HuH-7 Alters Drug Metabolism

*HuH-7 was the parental cell line with CYP3A5 *3/*3 alleles
*CYP3A5 *3/*3 pm was a bioengineered cell line with the CYP3A5 *1 allele made by deletion of a splice acceptor on one of the alleles.
*CYP3A5 *1/*1 pm was a bioengineered cell line with both CYP3A5 *1 alleles made by deletion of a splice acceptor on two of the alleles.
*CYP3A5 *1/*1 pm was a bioengineered cell line with the CYP3A5 *1 allele made by a point mutation of a splice acceptor on one of the alleles.

Fig. 8. CYP3CIDE-selective inhibition of CYP3A4 and CYP3A5 and dose response in cell lines. (A) CYP3CIDE inhibition of CYP3A4 and CYP3A5 enzymatic activity. CYP3CIDE has a higher affinity on CYP3A4 inhibition than on CYP3A5 inhibition. The substrate in this experiment was MDZ, and the products of the reactions were 1-OH MDZ and 4-OH MDZ. (B) CYP3CIDE dose-response curve in HuH-7 (CYP3A5 *3/*3) and CYP3A5 *1/*1 dd cell lines with the 1-OH MDZ product as metabolite. The concentration of 50 µM CYP3CIDE was chosen for further study in other cell lines.
that are different from those of HuH-7. The mutation, and these cell lines have either a 77-bp splice junction deletion or a point mutation. Other cell lines have been generated for comparative studies with the control HuH-7 cells; however, the two CYP3A5 *1/*3 heterozygote cell lines have either a 77-bp splice junction deletion or a point mutation, and these cell lines have CYP3A5 expression and activity that are different from those of HuH-7. The CYP3A5 *1/*1 dd was vastly more metabolically active than the other cell lines and would be the most useful for comparative studies with the CYP3A5 *1/*3 genotype.

Future work using these methods and developed cell lines includes a number of directions. We envision panels of cell lines developed using genetic modification that can be used to study genetic variants associated with drug metabolism. These panels could include variants of particular metabolism genes, gene families, common variants or combinations of variant alleles. The values of these panels could also be engineered into cell lines and used in preclinical drug metabolism screens to predict pharmacokinetics. Rare variants could also be engineered into the cell lines. If rare alleles were found to alter metabolism, such results may predict subjects at risk for drug failure or toxicity and may also allow for early testing of alternative doses for trial subjects carrying combination of variants or rare alleles. There are substantial challenges in studying rare alleles in human clinical trials owing to inadequate sample size; therefore, engineered cells could bring extreme value to drug development. In addition, drugs already on the market could be rapidly screened. Since the new cells in this study express CYP3A5, the cells are especially useful to studying genetic variants that effect CYP3A5 expression. Finally, it may also be possible that multiple variants could be engineered into a single cell line that would more closely emulate the specific human populations. This technology can potentially lead to faster preclinical development that can save time and money. As the use of this technology expands, we will be able to more accurately predict substrate metabolism, pharmacokinetics, toxicities, and efficacy, especially in minority patients with rare genetic variants.

Acknowledgments

The authors thank the University of Minnesota Genomics Center for numerous molecular biology services. Ajay Israni and Casey Dorr, along with Minneapolis Medical Research Foundation, have filed a provisional patent with the US Patent and Trademark Office titled: “Genetically Modified Cells for Metabolic Studies.” The patent application number is 62/459,749. The cell line CYP3A5 *1/*3 is deposited at American Type Culture Collection (ATCC) patent depository under the name “Human Liver Cell Line, 97 CYP3A5 *1/*3” with ATCC patent deposit designation PTA-123710.

Fig. 9. Effect of CYP3CIDE on MDZ metabolism in CYP3A5 genetically modified cells. Cells were treated with (gray bars) or without 50 μM CYP3CIDE (black bars) and assayed for MDZ metabolism. Each column in (C–E) represents six biologic replicates of a representative experiment. (C) MDZ disappearance by cell lines after incubation of 1-OH MDZ by cell lines in the presence of CYP3CIDE. P values in (C–E) were calculated based on the paired two-sample t test comparing with or without CYP3CIDE as ns, not significant; P > 0.05; *P ≤ 0.05; ***P ≤ 0.001.
