ABSTRACT

Polycyclic aromatic hydrocarbons (PAHs) are potent carcinogens and are a primary risk factor for the development of lung and other aerodigestive tract cancers in smokers. The detoxification of PAHs by glucuronidation is well-characterized for the UDP-glycosyltransferase (UGT) 1A, 2A, and 2B subfamilies; however, the role of the UGT3A subfamily in PAH metabolism remains poorly understood. UGT3A enzymes are functionally distinct from other UGT subfamilies (which use UDP-glucuronic acid as a cosubstrate) due to their utilization of alternative cosubstrates (UDP-N-acetylglucosamine for UGT3A1, and UDP-glucose and UDP-xylose for UGT3A2). The goal of the present study was to characterize UGT3A glycosylation activity against PAHs and examine their expression in human aerodigestive tract tissues. In vitro metabolism assays using UGT3A2-overexpressing cell microsomes indicated that UGT3A2 exhibits glycosylation activity against all of the simple and complex PAHs tested. The \( V_{\text{max}}/K_{\text{m}} \) ratios for UGT3A2 activity with UDP-xylose versus UDP-glucose as the cosubstrate ranged from 0.65 to 4.4 for all PAHs tested, demonstrating that PAH glycosylation may be occurring at rates up to 4.4-fold higher with UDP-xylose than with UDP-glucose. Limited glycosylation activity was observed against PAHs with UGT3A1-overexpressing cell microsomes. While UGT3A2 exhibited low levels of hepatic expression, it was shown by western blot analysis to be widely expressed in aerodigestive tract tissues. Conversely, UGT3A1 exhibited the highest expression in liver with lower expression in aerodigestive tract tissues. These data suggest that UGT3A2 plays an important role in the detoxification of PAHs in aerodigestive tract tissues, and that there may be cosubstrate-dependent differences in the detoxification of PAHs by UGT3A2.

SIGNIFICANCE STATEMENT

UGT3A2 is highly active against PAHs with either UDP-glucose or UDP-xylose as a cosubstrate. UGT3A1 exhibited low levels of activity against PAHs. UGT3A1 is highly expressed in liver while UGT3A2 is well expressed in extrahepatic tissues. UGT3A2 may be an important detoxifer of PAHs in humans.

INTRODUCTION

Tobacco smoke contains over 4800 compounds with at least 69 identifiable carcinogens (Hoffmann et al., 2001). One of the most potent and abundant groups of tobacco carcinogens are the polycyclic aromatic hydrocarbons (PAHs), which are classified as group 1, 2A, or 2B carcinogens by the International Agency for Research on Cancer (Hecht, 1999). In addition to being present in tobacco smoke, PAHs are produced by incomplete combustion of organic compounds including wood, coal, oil, and gasoline, and many food sources, and humans are exposed to PAHs on a regular basis through air, water, soil, and food sources by ingestion, inhalation, and dermal contact (Mumtaz et al., 2010). Smokers are exposed to higher levels of PAHs than nonsmokers, with urinary PAH metabolites 1.5- to 6.9-fold higher in smokers than in nonsmokers, with urinary PAH metabolites 1.5- to 6.9-fold higher in smokers than in nonsmokers (Suwan-ampai et al., 2009).

ABBREVIATIONS: BaP, benzo(a)pyrene; BaP-7,8-diol, trans-7,8-dihydroxy-7,8-dihydro-benzo(a)pyrene; BaP-9,10-diol, benzo(a)pyrene-trans-9,10-dihydrodiol; DBaP, dibenzo(a)pyrene; DBaP-11,12-diol, trans-11,12-dihydroxy-11,12-dihydribenzo(a)pyrene; HEK293, human embryonic kidney 293; 5-MeC, 5-methylchrysene; 5-McC-1,2-diol, 1,2-dihydro-1,2-dihydroxy-5-methylchrysene; 1-OH-pyrene, 1-hydroxypyrene; PAH, polycyclic aromatic hydrocarbon; PCR, polymerase chain reaction; TBS, Tris-buffered saline; UDP-Glc, UDP-glucose; UDP-GlcNAc, UDP-N-acetylglucosamine; UDP-GlcUA, UDP-glucuronic acid; UDP-Xyl, UDP-xylose; UGT, UDP-glycosyltransferase.
The major carcinogen activation pathway for PAHs is via the cytochrome P450 (CYP) class of enzymes, with biotransformation of BaP by several CYP enzymes, including 1A1 and 1B1, to form hydroxylated or epoxide forms (Shimada et al., 1996; Kim et al., 1998). BaP epoxides are hydrolyzed by microsomal epoxide hydrolase to form BaP-diols, which can undergo further metabolism by CYP1A1, 1B1, and 3A4 to BaP-diol-epoxides, many of which are capable of forming PAH-DNA adducts (Thakker et al., 1977; Levin et al., 1980; Trushin et al., 2012). The carcinogeticity of PAHs is dependent on the number of benzenoid rings, their ring structure (fjord vs. bay regions), and having metabolites that can form DNA adducts (Moorthy et al., 2015; Gao et al., 2018). DBaP is the most carcinogenic PAH because it has a fjord region that is nonplanar, reactive, and binds preferentially to adenine nucleotides (Ewa and Danuta, 2017). In contrast, 5-MeC and BaP have a bay region that is planar, less reactive, and binds to guanine nucleotides; 5-MeC is more carcinogenic than BaP because it has a methylated bay region and an additional bay region (Palackal et al., 2002; Ewa and Danuta, 2017).

A major mode of detoxification of PAHs is by the phase II family of UDP-glycosyltransferases (UGTs). While extensive studies have examined the UGT1A, 2A, and 2B enzyme subfamilies for activity against PAHs (Jin et al., 1993; Fang et al., 2002; Uchaipichat et al., 2004; Finel et al., 2005; Luukkanen et al., 2005; Dellinger et al., 2006; Itäaho et al., 2010; Bushey et al., 2011; Olson et al., 2013), few studies have examined the activity of UGT3A enzymes against these carcinogetic compounds. Unlike other UGT enzymes which use UDP-glucuronic acid (UDP-GlcUA) as a cosubstrate, the UGT3A enzymes are unique from other UGTs in that they use alternative sugars as cosubstrates, with UGT3A1 using UDP-N-acetylglucosamine (UDP-GlcNAc) and UGT3A2 using UDP-glucose (UDP-Glc) or UDP-xylene (UDP-Xyl) (Mackenzie et al., 2008, 2011).While UGT3A1 was shown to be expressed in liver and kidney and to a lesser extent in testes, colon, and duodenum, UGT3A2 was found to be primarily an extrahepatic enzyme (Mackenzie et al., 2008, 2011).

In a screening of their activity against a variety of substrates, UGT3A1 and 3A2 both exhibited glycosylic activity against the simple PAHs 1-naphthol and 1-hydroxyphenyl (1-OH-pheny) (Mackenzie et al., 2008, 2011; Meech and Mackenzie, 2010; Meech et al., 2011). In a screening of their activity against a variety of substrates, UGT3A1 and 3A2 both exhibited glycosylic activity against the simple PAHs 1-naphthol and 1-hydroxyphenyl (1-OH-pheny) (Mackenzie et al., 2008, 2011; Meech and Mackenzie, 2010; Meech et al., 2011). The goals of the present study were to better characterize UGT3A activity against more complex PAHs and to examine their expression in human aerodigestive tract tissues, which are target sites of PAH carcinogeticity.

Materials and Methods

Chemicals and Reagents. The RNeasy Mini Kit was purchased from Qiagen (Valencia, CA). SuperScript II reverse transcriptase, Platinum Taq DNA polymerase, the pCDNA3.1/V5-His TOP1 TA Expression Kit, One Shot TOP10 competent Escherichia coli, Lipofectamine 2000, the PureLink Genomic DNA Mini Kit, InvitroLink Polynucleotides diphosphoFilter Paper Sandwich, and the Novex ECL Chemiluminescent Substrate Reagent Kit were obtained from Life Technologies (Carlsbad, CA). Oligonucleotides for polymerase chain reaction (PCR) were purchased from Integrated DNA Technologies (Coralville, IA). The GeneJet Gel Extraction and DNA Cleanup Micro Kit, GeneJet Plasmid Mini and Midi Kit, Pierce BCA Protein Assay kit, and Gelcode Blue Stain Reagent were purchased from Thermo Scientific (Waltham, MA). DuBecco’s modified Eagle’s medium, DuBecco’s PBS, and genetin were purchased from GIBCO (Grand Island, NY). Premium grade PBS was purchased from SERADIN (Radnor, PA) and Chromatopur bovine albumin was purchased from MB Biomedicals (Santa Ana, CA).

The UGT3A antibody was purchased from Santa Cruz Biotechnology (Dallas, TX), while donkey anti-goat IgG horseradish peroxidase conjugate, anti-β-actin, rabbit anti-mouse IgG horseradish peroxidase conjugate, and goat anti-rabbit horseradish peroxidase conjugate were purchased from Thermo Fisher Scientific (Rockford, IL). UDP-Glc and anti-UGT3A1 antibody were purchased from Abcam (Cambridge, MA). UDP-Xyl was purchased from Carbosource Services (Athens, GA). 1-OH-pheny, 1-naphthol, amelaminic, ampicillin, UDP-GlcNAc, and β-N-acyetylglucosaminidase were purchased from Sigma-Aldrich (St. Louis, MO). β-Glucosidase and exo-1,4-β-D-xylodulcose were purchased from Megazyme (Bry, Ireland). 1-OH-BaP, 7-OH-BaP, 8-OH-BaP, 9-OH-BaP, B(a)P-trans-9,10-dihydriodiol (B(a)P-9,10-diol), trans-11,12-dihydriodiol-11,12-dihydriodibenzo(a)pyrene (B(a)P-11,12-diol), and 1,2-dihydriod-1,2-dihydriod-5-methylchlyocene (5-MeC-1,2-diol) were purchased from MRI Global (Kansas City, MO). 3-OH-BaP and trans-7,8-dihydriod-7,8-dihydro-B(a)P (B(a)P-7,8-diol) were purchased from Toronto Research Chemicals (North York, ON, Canada). High-performance liquid chromatography grade ammonium acetate and Optima acetonitrile were purchased from Fisher Scientific (Pittsburgh, PA).

Tissues. Normal human tissue specimens were obtained from the Banner Health Research Institute (Sun City, AZ), the Cooperative Human Tissue Network Eastern Division (Philadelphia, PA), or the H. Lee Moffit Cancer Center (Tampa, FL), and were isolated postmortem within 3 hours and frozen at −80°C. Mixed tissues selected for this study were primarily from the respiratory tract [lung (n = 5), trachea (n = 4), tongue (n = 3), floor of mouth (n = 2), tonsil (n = 5), larynx (n = 4), and esophagus (n = 5)], digestive tract [jejenum (n = 5), colon (n = 5), and liver (n = 5)], and breast (n = 5). The demographic information for these human tissues is described in Supplemental Table 1. Of the tissue samples where demographic information was obtained, 51% were female, with 80% from Whites and 20% from Blacks.

Normal human kidney total RNA was purchased from Stratagene (La Jolla, CA); total RNA was extracted using standard protocols from normal human liver tissue obtained from the Penn State University College of Medicine Tissue Bank. All protocols involving the analysis of tissue specimens from these tissue banks were approved by the institutional review board at Washington State University in accordance with assurances filed with and approved by the U.S. Department of Health and Human Services.

Generation of UGT3A1-Overexpressing Cell Lines. A stable human embryonic kidney 293 (HEK293) cell line overexpressing UGT3A1 was generated using standard protocols. Normal human liver total RNA (2 μg) was extracted using an RNasey Mini Kit from normal human liver tissue, which was used as a template in a reverse transcription reaction containing Superscript II reverse transcriptase (200 U). cDNA corresponding to 200 ng total liver RNA was used with 2.5 μU of Platinum Taq DNA polymerase for the PCR amplification of UGT3A1. The primers used to amplify UGT3A1 from liver cDNA were 5′-TTC-TGTGAATGTCAGCTTTGTT-3′ (sense) and 5′-AGGCTTATGTCCTTCTGACCTT-3′ (antisense), corresponding to nucleotides −19 to +5 and +1576 to +1554, respectively, relative to the UGT3A1 translation start site. PCR was performed with an initial denaturation temperature of 94°C for 2 minutes, 40 cycles of 94°C for 30 seconds, 57°C for 40 seconds, and 72°C for 1 minute and 45 seconds, followed by a final cycle of 10 minutes at 72°C. The UGT3A1 sequence was verified by Sanger sequencing (Genewiz, South Plainfield, NJ) and compared with that described for UGT3A1 in GenBank (NM_152404.3). The sequencing results revealed that the UGT3A1 insert contained a synonymous C1320T nucleotide change, which maintained the alanine at amino acid residue 430. The UGT3A1 insert was cloned into a pCDNA3.1/V5-His-TOPO vector using standard protocols. After transformation using One Shot TOP10 competent E. coli, transformants were grown on plates containing LB agar and ampicillin (100 μg/ml) and confirmed by Sanger sequencing. Lipofectamine 2000 was used to transfet 8 μg of pCDNA3.1/V5-His-TOPO/UGT3A1 plasmid into HEK293 cells purchased from American Type Culture Collection (Manassas, VA). The HEK293 cell line was authenticated by American Type Culture Collection using short-tandem repeat polymorphisms analysis in December 2017. Stable cell lines were grown in Dulbecco’s modified Eagle’s medium supplemented with 10% FBS and 700 μg/ml of geneticin. Genomic DNA was extracted from the stable cell line using the PureLink Genomic DNA Mini Kit and Sanger sequencing was used to confirm the presence and identity of the UGT3A1 cDNA sequence.

The UGT3A2 overexpressing HEK293 cell line was generated by reverse transcription PCR as described previously using normal human total kidney RNA (2 μg) as the template for reverse transcription. The primers used to amplify UGT3A2 from kidney cDNA were 5′-GGTTCTCCCTGAAGTGACGCAGTCTG-3′ (sense) and 5′-CTCTGGCTCTATGCTCTTCACC-3′ (antisense), corresponding to nucleotides −19 to +3 and +1579 to +1557, respectively, relative to the
UGT3A2 translation start site. PCR was performed with an initial denaturation temperature of 94°C for 2 minutes, 40 cycles of 94°C for 30 seconds, 57°C for 40 seconds, and 72°C for 2 minutes, followed by a final cycle of 10 minutes at 72°C. The PCR product was excised and purified from an agarose gel using the GeneJel Gel Extraction Kit. The purified PCR product was verified by Sanger sequencing and was found to be identical to the reference UGT3A2 cDNA sequence (NM_174914.3). The verified UGT3A2 cDNA was cloned into the pcDNA3.1/V5-His-TOP expression vector and overexpressed in HEK293 cells as described previously for UGT3A1. The UGT3A2-overexpressing HEK293 cell line was verified by Sanger sequencing.

**Analysis of UGT3A Protein Expression.** For UGT-overexpressing cell lines, whole cell homogenates and S9 and microsomal fractions were prepared through differential centrifugation utilizing methods adapted from a previous study (Dellinger et al., 2007). Briefly, cell homogenates were prepared by resuspending pelleted cells in Tris-buffered saline (TBS; 25 mM Tris base, 138 mM NaCl, and 2.7 mM KCl (pH 7.4)), followed by five rounds of freeze-thaw cycles prior to gentle homogenization. The S9 fraction was prepared by centrifuging the cell homogenate at 9000g for 30 minutes at 4°C. The S9 fraction was further processed by ultracentrifugation at 105,000g for 1 hour at 4°C, and the microsomal pellet was resuspended in TBS. Total protein concentrations were determined using the Pierce BCA Protein Assay Kit.

Western blot analysis was performed using 20 μg of total protein homogenate utilizing a 10% SDS-polyacrylamide gel, which was subsequently transferred to an Invitronol Polyvinylidene difluoride membrane. For UGT3A1, membranes were blocked with a 5% solution of milk in TBS containing 0.1% Tween 20 and probed with a rabbit monoclonal UGT3A1 antibody (1:1500 dilution), followed by a goat anti-rabbit secondary antibody (1:1000 dilution). For UGT3A2, the membrane was blocked with a 5% solution of ChrotoPur bovine albumin in TBS containing 0.1% Tween 20 and probed with goat polyclonal UGT3A2 antibody (1:1000 dilution), followed by a donkey anti-goat secondary antibody (1:2500 dilution). The β-actin antibody (1:5000 dilution) was used to verify equal loading using the rabbit anti-mouse secondary antibody (1:10,000 dilution) for both the UGT3A1 and UGT3A2 western blots. Immunocomplexes were visualized with the Novex ECL Chemiluminescent Kit following the manufacturer’s protocols.

Tissues were homogenized with a Qiagen Tissuelyser II (Hilden, Germany) in 2 ml tubes with a 5 mm bead at 22 Hz for 2 minutes. S9 fractions were prepared using TBS by centrifugation at 9000g for 30 minutes at 4°C. Western blot analysis was performed using 20 μg of S9 fractions that were analyzed as described previously for the UGT-overexpressing cell lines. Loading variability was monitored by Coomassie blue staining. Gelcode Blue Stain Reagent was used to detect total protein for normalization by densitometry analysis using Image J software (https://image.j.nih.gov/ij/; National Institutes of Health, Bethesda, MD).

**Glycosylation Assays and Analysis.** To screen for glycosylation activity for both UGT3A enzymes, incubations were performed with alternative sugars using a method adapted from a previous study (Bushey et al., 2011). Microsomes (10–100 μg total protein) from the HEK293- or UGT3A2-overexpressing HEK293 cell lines were incubated with alaminchalin (=0 μg/mg total protein) for 15 minutes on ice. Glycosylation reactions were performed with 200–800 μM substrate, 50 mM Tris-HCl (pH 7.4), 10 mM MgCl2, and 4 mM UDP-GlcNAc, 15 minutes on ice. Glycosylation reactions were performed with 200 μg of S9 fractions that were analyzed as described previously for the UGT-overexpressing cell lines. Loading variability was monitored by Coomassie blue staining. Gelcode Blue Stain Reagent was used to detect total protein for normalization by densitometry analysis using Image J software (https://image.j.nih.gov/ij/; National Institutes of Health, Bethesda, MD).

**Results**

**Expression of UGT3A Enzymes in Human Tissues.** In the current study, UGT3A1 and UGT3A2 expression was analyzed in a comprehensive panel of aerodigestive tract tissues. As shown by western blots of UGT3A1- and UGT3A2-overexpressing cell lines, there was no crossreactivity of the UGT3A1 (Fig. 1A) or UGT3A2 (Fig. 1B) antibodies with any of the other UGTs tested. The molecular weight of both recombinant UGT3A proteins was approximately 53 kDa, as reported previously (MacKenzie et al., 2008, MacKenzie et al., 2011).

Representative western blots showed that both UGT3A1 and 3A2 were expressed in all tissues tested (Fig. 1, C and D, respectively). Densitometry analysis showed that the relative expression of UGT3A1 was highest in liver (used as the reference at 1.0), followed by bile, jejunum, and larynx (approximately 0.30 for each) > trachea (0.20) > lung, breast, and colon (approximately 0.14 for each) > tonsil and esophagus (approximately 0.040 for both) > heart of mouth (0.025) (Fig. 1E). The relative expression for UGT3A2 was highest in the heart of the oral cavity (used as the reference at 1.0), followed by trachea and larynx (approximately 0.70 for both) > esophagus, tonsil, and colon (approximately 0.50 for each) > jejunum (0.30) > liver (0.21) (Fig. 1F).

**Glycosylation of PAHs by UGT3A Enzymes.** Microsomal protein from the UGT3A1- and UGT3A2-overexpressing HEK293 cell lines was used to screen for activity against the following PAHs: 1-OH-pyrene, 1-naphthol, 1-OH-BaP, 3-OH-BaP, 7-OH-BaP, 8-OH-BaP, 9-OH-BaP, DBaP/11,12-diol, and 5-MeC-1,2-diol. In vitro glycosylation assays using UDP-GlcNAc as cosubstrate showed UGT3A1 activity against 1-OH-pyrene, a known UGT3A substrate (Meech and Mackenzie, 2010), to form the pyrenyl-1-O-GlcNAc conjugate (retention time: 3.78 minutes) (Fig. 2A). UGT3A1-overexpressing microsomes also demonstrated
activity against 8-OH-BaP (Fig. 2B) and BaP-9,10-diol (Fig. 2C). Two GlcNAc conjugates were observed for BaP-9,10-diol (retention times: 3.28 and 3.34 minutes), likely representing N-acetylglucosaminides at the 9- and 10-diol positions. Detectable glycosylation activity for UGT3A1-overexpressing microsomes was not observed for any other PAH tested using up to 100 µg microsomal protein. No glycosylation was observed for microsomes from the parent HEK293 cell line for 1-OH-pyrene, 8-OH-BaP, or BaP-9,10-diol using UDP-GlcNAc as cosubstrate (Fig. 2, A–C) or when using either UDP-Glc, UDP-Xyl, or UDP-GlcUA as cosubstrate (data not shown).

In vitro glycosylation assays with UGT3A2-overexpressing microsomes showed UGT3A2 activity against all of the PAHs tested using UDP-Glc as cosubstrate. In addition to 1-OH-pyrene, UGT3A2-overexpressing microsomes exhibited high activity against the simple PAHs (1-OH-BaP, 3-OH-BaP, 7-OH-BaP, and 9-OH-BaP) to form glucoside metabolites with a range of retention times from 3.84 to 4.26 minutes (Fig. 3, A–C, for 1-OH-pyrene, 1-OH-BaP, and 9-OH-BaP, respectively). More moderate activity was observed for UGT3A2-overexpressing microsomes against 1-naphthol (data not shown). Less overall activity was observed for UGT3A2-overexpressing microsomes against 8-OH-BaP and BaP-9,10-diol (Fig. 2B) and BaP-9,10-diol (Fig. 2C).

Fig. 1. Western blot analysis of UGT3A1 and 3A2 protein expression in HEK293 overexpressing cell lines and human tissues. (A) Antibody against UGT3A1 was analyzed for specificity for the UGT3A1-overexpressing HEK293 cell line, and possible crossreactivity with the empty HEK293 parent cell line and cell lines overexpressing UGT1A1, 1A9, 3A2, 2B7, 2B17, and 2A1 using total protein homogenate (20 µg). β-Actin was used as a loading control. (B) Antibody against UGT3A2 was analyzed for specificity for the UGT3A2-overexpressing HEK293 cell line, and possible crossreactivity with empty HEK293 parent cell line and cell lines overexpressing UGT3A1, 1A1, 1A9, 2A1, 2B7, and 2B17 using total protein homogenate (20 µg). β-Actin was used as a loading control. (C) Representative western blot of UGT3A1 protein expression of S9 fractions of various human tissues (n = 2–5 specimens for each tissue site). The S9 fraction of UGT3A1-overexpressing HEK293 cells was used as a positive control, and the S9 fraction of the HEK293 parent cell line was used as a negative control. Total protein stain was used to normalize expression in tissues. (D) Representative western blot of UGT3A2 protein expression of S9 fraction in various human tissues (n = 2–5 specimens for each tissue site). The S9 fraction of UGT3A2-overexpressing HEK293 cells was used as a positive control, and the S9 fraction of the HEK293 parent cell line was used as a negative control. Total protein stain was used to normalize expression in tissues. (E) Relative UGT3A1 protein expression was quantified by comparing protein levels in each tissue with the tissue exhibiting the highest UGT3A1 expression (i.e., liver). (F) Relative UGT3A2 protein expression was quantified by comparing protein levels in each tissue with the tissue exhibiting the highest UGT3A2 expression (i.e., floor of mouth). (E and F) Relative amounts are expressed as the mean ± S.E. to account for the number of tissues analyzed in each group (n = 2–5 specimens for each tissue site).
against more complex PAHs including BaP-7,8-diol (conjugate retention time: 3.80 minutes) (Fig. 3D) and BaP-9,10-diol (two conjugates retention times: 3.35 and 3.41 minutes) (Fig. 3E). Similar levels of activity were observed for UGT3A2-overexpressing microsomes against DबαlP-11,12-diol (conjugate retention time: 4.05 minutes) (Fig. 3F) and 5-MeC-1,2-diol (data not shown). No glycosylation was observed for microsomes from the parent HEK293 cell line for all PAHs tested using UDP-Glc (Fig. 3), UDP-Xyl (Fig. 4), UDP-GlcNAc (data not shown), or UDP-GlUA (data not shown) as cosubstrates.

A similar pattern of activity was observed for UGT3A2-overexpressing microsomes when using UDP-Xyl as the cosubstrate in vitro glycosylation activity assays, with high activity observed against 1-OH-pyrene, 1-OH-B₇, 3-OH-B₂P, 7-OH-B₂P, and 9-OH-B₂P (Fig. 4, A–C, for 1-OH-pyrene, 1-OH-B₂P, and 9-OH-B₂P, respectively). Again, less overall activity was observed for UGT3A2-overexpressing microsomes against more complex PAHs, with peaks corresponding to xyloside conjugates observed for UGT3A2-overexpressing microsomes at 4.05 minutes for BaP-7,8-diol (Fig. 4D), 3.49 and 3.59 minutes for BaP-9,10-diol (Fig. 4E), and 4.44 minutes for DBαlP-11,12-diol (Fig. 4F). Glycosylated metabolites were confirmed by sensitivity to glycosidases, with cleavage of the sugar observed for 1-OH-pyrene, 1-OH-B₇, and 9-OH-B₂P after treatment with β-glucosidase (Supplemental Fig. 1, A–C) or β-xylosidase (Supplemental Fig. 1, D–F).

Kinetic Studies of PAHs by UGT3A Enzymes. After screening for UGT3A1 activity against all PAH substrates, kinetic parameters were determined for 1-OH-pyrene, 8-OH-B₇, and BaP-9,10-diol using UDP-GlcNAc as the cosubstrate, with representative Michaelis-Menten kinetic curves shown in Fig. 2, D–F. Kinetic assays using the UGT3A1-overexpressing HEK293 cell microsomes with UDP-GlcNAc exhibited the highest activity for BaP-9,10-diol ($V_{\text{max}}/K_m = 0.048 \pm 0.010 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) (Fig. 2F) followed by 1-OH-pyrene ($V_{\text{max}}/K_m = 0.010 \pm 0.0019 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) (Fig. 2D). Exact kinetic values could not be obtained for 8-OH-B₂P ($K_m > 1600 \mu\text{M}$, $V_{\text{max}} > 25 \mu\text{mol} \cdot \text{min}^{-1} \cdot \mu\text{g}^{-1}$) since the rate of BaP-8-O-GlcNAc formation did not reach saturation using up to 1600 µM substrate (Fig. 2E).

After screening for activity against the PAH substrates, kinetic parameters were determined for UGT3A2 using UDP-Glc or UDP-Xyl as cosubstrates. Representative Michaelis-Menten kinetic curves are shown for simple PAHs in Fig. 5, A–C and complex PAHs in Fig. 5, D–F using both cosubstrates. When using UDP-Glc as the cosubstrate, UGT3A2-overexpressing microsomes exhibited the highest activity for 1-OH-pyrene ($V_{\text{max}}/K_m = 396 \pm 52 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$), with high levels of activity also observed for 3-OH-B₂P ($V_{\text{max}}/K_m = 238 \pm 51 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) and 1-OH-B₂P ($V_{\text{max}}/K_m = 202 \pm 54 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) (Table 1). Slightly lower overall activity was observed for 9-OH-B₂P ($V_{\text{max}}/K_m = 84 \pm 47 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) and 7-OH-B₂P ($V_{\text{max}}/K_m = 62 \pm 6 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$).

Lower levels of activity were observed for 1-naphthol ($V_{\text{max}}/K_m = 2.2 \pm 0.40 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$), DBαlP-11,12-diol ($V_{\text{max}}/K_m = 0.074 \pm 0.0058 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$), BaP-7,8-diol ($V_{\text{max}}/K_m = 0.034 \pm 0.0059 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$), 5-MeC-1,2-diol ($V_{\text{max}}/K_m = 0.031 \pm 0.0047 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$), and BaP-9,10-diol ($V_{\text{max}}/K_m = 0.0087 \pm 0.00069 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$).

A similar pattern was observed for UGT3A2-overexpressing microsomes when using UDP-Xyl as the cosubstrate. The highest level of activity was again observed against simple PAHs including 1-OH-pyrene ($V_{\text{max}}/K_m = 840 \pm 254 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) > 3-OH-B₂P ($V_{\text{max}}/K_m = 389 \pm 98 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) > 1-OH-B₂P ($V_{\text{max}}/K_m = 199 \pm 53 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) > 9-OH-B₂P ($V_{\text{max}}/K_m = 129 \pm 10 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) > 7-OH-B₂P ($V_{\text{max}}/K_m = 80 \pm 26 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) > 1-naphthol ($V_{\text{max}}/K_m = 3.54 \pm 0.28 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) (Table 1). Less overall activity was observed for the complex PAHs, with the highest level of activity observed for BaP-7,8-diol ($V_{\text{max}}/K_m = 0.11 \pm 0.011 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$), followed by DBαlP-11,12-diol ($V_{\text{max}}/K_m = 0.051 \pm 0.0015 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) > BaP-9,10-diol ($V_{\text{max}}/K_m = 0.038 \pm 0.010 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$) > 5-MeC-1,2-diol ($V_{\text{max}}/K_m = 0.020 \pm 0.0041 \mu\text{mol} \cdot \text{min}^{-1} \cdot \text{mg}^{-1}$).
Except for 1-naphthol, the $K_m$ value was at least an order of magnitude lower for the simple PAHs compared with the more complex PAHs, reaching 379-fold lower for 1-OH-pyrene compared with 5-MeC-1,2-diol when using UDP-Glc as the cosubstrate, and 140-fold lower for 1-OH-pyrene compared with BaP-7,8-diol when using UDP-Xyl as the cosubstrate. A significantly ($P < 0.05$) higher level of activity ($V_{\text{max}}/K_m$) was observed for UGT3A2-overexpressing microsomes with UDP-Xyl as the cosubstrate compared with assays with UDP-Glc as the cosubstrate for 1-naphthol, 9-OH-BaP, BaP-7,8-diol, BaP-9,10-diol, and DBaP-11,12-diol, with the UDP-Xyl/UDP-Glc $V_{\text{max}}/K_m$ ratio reaching up to 4.4-fold for BaP-9,10-diol (Table 1).

**Discussion**

The role of the UGT3A subfamily in carcinogen metabolism has been understudied when compared with members of the UGT1A, 2A, and 2B
Fig. 5. Representative Michaelis-Menten kinetic curves of PAH conjugate formation for UGT3A2 using either UDP-Glc or UDP-Xyl as the cosubstrate. (A–F) Representative Michaelis-Menten kinetic curves of PAH conjugate formation for UGT3A2 with 1-OH-pyrene (A), 1-OH-B(a)P (B), 9-OH-B(a)P (C), B(a)P-7,8-diol (D), B(a)P-9,10-diol (E), and DB(a)P-11,12-diol (F). Michaelis-Menten kinetic curves are represented by solid black circles and black lines for UDP-Glc; the open blue circles and blue dashed lines represent UDP-Xyl.

subfamilies, with UGT3A1 and 3A2 having previously been shown to exhibit activity against the simple PAHs 1-naphthol and 1-OH-pyrene (Mackenzie et al., 2008; MacKenzie et al., 2011; Meech and Mackenzie, 2010; Meech et al., 2012). In the present study, UGT3A1 was confirmed to exhibit activity against 1-OH-pyrene, and it also exhibited glycosylation activity against 8-OH-B(a)P and B(a)P-9,10-diol. However, no detectable activity was observed for UGT3A1 against any other PAH tested. While UGT3A1 exhibited low activity against the three PAHs, this activity was approximately 5-fold higher (i.e., \( V_{\text{max}}/K_m \)) against the more complex PAH, B(a)P-9,10-diol than against 1-OH-pyrene.

A different pattern was observed for UGT3A2, with relatively high glycosylation activity against all of the PAHs tested when either UDP-Glc or UDP-Xyl was used as the cosubstrate. The activity of UGT3A2 was higher against the simple PAHs, with the \( V_{\text{max}}/K_m \) ratios ranging from 644- to 12,774-fold higher for 1-OH-pyrene, 1-OH-B(a)P, 3-OH-B(a)P, 7-OH-B(a)P, and 9-OH-B(a)P compared with the more complex PAHs including B(a)P-7,8-diol, B(a)P-9,10-diol, DB(a)P-11,12-diol, and 5-MeC-1,2-diol when UDP-Glc was used as the cosubstrate, and 727- to 42,000-fold higher when UDP-Xyl was used as the cosubstrate. The only simple PAH that UGT3A2 exhibited modest activity against was 1-naphthol, which exhibited a \( V_{\text{max}}/K_m \) ratio that was 23- to 25-fold lower with either UDP-Glc or UDP-Xyl as the cosubstrate than that observed for 7-OH-B(a)P, the simple PAH against which UGT3A2 exhibited the next lowest activity.

UGT3A2 using UDP-Xyl as the cosubstrate exhibited approximately equivalent or slightly lower \( K_m \) values than when using UDP-Glc as the cosubstrate against all PAHs tested, except for DB(a)P-11,12-diol. Similarly, the \( V_{\text{max}}/K_m \) ratios observed for UGT3A2 with UDP-Xyl as the cosubstrate were similar to or higher than assays with UDP-Glc as the cosubstrate.

*Data are expressed as milligrams of total microsomal protein. The \( K_m \), \( V_{\text{max}} \), and \( V_{\text{max}}/K_m \) values represent the mean ± S.D. of three independent experiments.

*\( P < 0.05 \) vs. corresponding value for UGT3A2-overexpressing microsomes using UDP-Glc as the cosubstrate.
the cosubstrate. These data suggest that both sugars may be used equally efficiently by UGT3A2 for the conjugation of PAHs.

In the present study, modest relative expression was observed for UGT3A1 protein in aerodigestive tract tissues including tongue, lung, larynx, jejunum, trachea, and colon. The expression observed for UGT3A1 protein in human lung in the present study contrasts with the lack of UGT3A1 mRNA expression found in human lung in a previous study (Mackenzie et al., 2008). Relatively low UGT3A1 protein expression was observed in several other aerodigestive tract tissues including tonsil, esophagus, and floor of mouth. The relatively high expression of UGT3A1 found in human liver in the present study confirms the relatively high hepatic expression found for UGT3A1 mRNA in a previous study (Mackenzie et al., 2008).

Relatively high expression of UGT3A2 protein was observed in all aerodigestive tract tissues examined in the present study, with the highest expression observed in floor of mouth, trachea, larynx and tongue. The lowest relative expression of UGT3A2 protein was observed in human liver. This pattern was similar to the higher levels of UGT3A2 mRNA detected in trachea, lung, and colon than observed in liver in a previous study (MacKenzie et al., 2011). However, while UGT3A2 was found to be expressed in both liver and esophagus in the present study, UGT3A2 mRNA was not detected in either tissue in previous studies, potentially due to issues involving mRNA quality, lack of homogeneity between different tissue specimens, or the sensitivity of methods used for the different studies (MacKenzie et al., 2011).

Large differences in expression were observed between specimens for several tissue sites in this study. While this could be due to interindividual expression differences, which could potentially play a role in susceptibility to PAH-induced carcinogenesis, this could also be due to differences in cell composition between samples. For example, the 188-fold range in UGT3A1 expression for breast could be due to composition differences in epithelial and stromal cells, collagen, and fat (Boyd et al., 2010). Further studies using laser-dissected specimens will be required to better analyze this possibility.

UDP sugars are used in glycosylation reactions in the lumen of the endoplasmic reticulum and Golgi apparatus, but in addition they can also be used to form proteoglycans and glycoproteins and participate in cell signal transduction, protein targeting, intercellular communication, and recognition of pathogens (Bertozzi and Kessler, 2001; Arase et al., 2009; Lazarowski and Harden, 2015). While differences in tissue or circulating UDP-sugar concentrations could potentially affect the activities of the different UGT enzymes against PAHs and other substrates, only limited studies have reported on the concentrations of UDP sugars in humans. UDP-Glc is converted by UDP-Glc-6-dehydrogenase to UDP-GlcUA, which can then be converted to UDP-Xyl by UDP-glucuronate decarboxylase (Harper and Bar-Peled, 2002). UDP-Xyl potentially inhibits UDP-Glc-6-dehydrogenase, which could affect the conversion of UDP-Glc to UDP-GlcUA in some tissues (Gainey and Phelps, 1972). UDP-Glc and UDP-GlcNAc exhibit higher concentrations than UDP-GlcUA in normal human breast tissue, with all UDP sugars increasing in concentration in breast cancer tissue (Oikari et al., 2018). Higher concentrations were observed for UDP-Glc than for UDP-Xyl in several animal tissues (Hardingham and Phelps, 1968; Handley and Phelps, 1972). An additional study reported levels of UDP-Glc (73 μM) > UDP-GlcUA (28 μM) > UDP-galactose (24 μM) > UDP-Xyl (7.0 μM) in sheep nasal septum cartilage (Gainey and Phelps, 1972).

Previous studies have examined UGT2B expression in lung, showing that UGT2B11 and 2B17 exhibit the highest levels of expression, accounting for 49% and 30% of total lung UGT2B expression, respectively (Jones and Lazarus, 2014). Other studies suggested that UGT1A6 exhibited the highest level of expression in lung of any UGT enzyme, accounting for 39% of total UGT expression, with UGT1A1, 1A8, and 2A1 also accounting for 10%–25% of total lung expression (Nishimura and Naito, 2006). The UGTs that have shown some level of expression in lung that exhibit PAH activity are 1A1, 1A4, 1A5, 1A6, 1A9, 1A10, 2A1, 2A3, 2B7, 2B15, and 2B17, with 1A4 and 1A5 only shown to exhibit activity against 1-OH-pyrene (Jin et al., 1993; Münzel et al., 1996; Fang et al., 2002; Uchaipichat et al., 2004; Finel et al., 2005; Luukkanen et al., 2005; Dellinger et al., 2006; Nishimura and Naito, 2006; Nakamura et al., 2008; Itiāho et al., 2010; Bushey et al., 2011, 2013; Olson et al., 2011; Jones and Lazarus, 2014). Of these, UGT1A10 and 2A1 exhibited some of the lowest Km values against PAHs (Dellinger et al., 2006; Bushey et al., 2011). UGT3A2-mediated glycosylation with UDP-Xyl exhibited lower or similar Km values than these UGTs against many of the PAHs tested in the present study. A 9-fold lower Km value (1.2 μM) for 1-OH-pyrene and a 4-fold lower Km value (9.6 μM) for 9-OH-BaP were observed for UGT3A2 with UDP-Xyl as the cosubstrate than that observed for UGT1A10 with UDP-GlcUA as the cosubstrate (11 and 38 μM, respectively) (Dellinger et al., 2006). UGT3A2 also exhibited comparable Km values for 3-OH-BaP (7.2 μM vs. 9.7 μM), 7-OH-BaP (8.5 μM vs. 9.8 μM), and BaP-7,8-diol (168 μM vs. 183–189 μM) compared with that observed previously for UGT1A10 (Fang et al., 2002; Dellinger et al., 2006). Similarly, the Km values for UGT3A2-mediated glycosylation of 1-OH-BaP and 5-MeC-1,2-diol with UDP-Xyl as the cosubstrate were 40- and 2.2-fold lower than that observed previously for UGT2A1 with UDP-GlcUA as the cosubstrate (6.1 μM vs. 247 μM and 124 μM vs. 270 μM, respectively) (Bushey et al., 2011). With UDP-Glc as the cosubstrate, the Km value was lower for UGT3A2 for five PAHs when compared with other UGTs (using UDP-GlcUA as the cosubstrate), including 1-OH-pyrene, 1-OH-BaP, 3-OH-BaP, 7-OH-BaP, and 9-OH-BaP (Dellinger et al., 2006; Bushey et al., 2011).

All of the UGT enzymes, previous studies had shown that UGT1A10 exhibited the lowest Km values against PAHs, and these values were in general very comparable to that observed for UGT3A2 in the present study. UGT1A10, like UGT3A2, is well expressed in a variety of aerodigestive tract tissues, suggesting that both UGT3A2 and 1A10 may be important enzymes for the detoxification of PAHs in these tissues (Mojarrabi and Mackenzie, 1998; Strassburg et al., 1999; Zheng et al., 2002; Dellinger et al., 2006; Nakamura et al., 2008). However, UGT3A2 is well expressed in lung while only one study has shown UGT1A10 to be expressed in lung (Dellinger et al., 2006). The other UGT enzyme that is well expressed in lung and exhibits relatively high glycosylating activity against PAHs is UGT2A1 (Bushey et al., 2011). Therefore, both UGT3A2 and 2A1 may be important in the detoxification of PAHs in lung.

In summary, UGT3A1 and 3A2 were shown to be expressed in all of the aerodigestive tract tissues tested. UGT3A2 was significantly more active than UGT3A1 against all PAHs tested and exhibited the lowest Km values against seven of the 10 PAHs tested in this study compared with that observed in previous studies for other UGTs. This high level of activity was observed when using either UDP-Glc or UDP-Xyl as the cosubstrate. These data suggest that UGT3A2 plays an important role in the detoxification of PAHs in target tissues like tissues of the aerodigestive tract. These data also suggest that PAHs could potentially be detoxified by various UGT enzymes using different cosubstrates.
