ABSTRACT

Doxorubicin is a widely used cancer therapeutic, but its effectiveness is limited by cardiotoxic side effects. Evidence suggests cardiotoxicity is due not to doxorubicin, but rather its metabolite, doxorubicinol. Identification of the enzymes responsible for doxorubicinol formation is important in developing strategies to prevent cardiotoxicity. In this study, the contributions of three murine candidate enzymes to doxorubicinol formation were evaluated: carbonyl reductase (Cbr) 1, Cbr3, and thioredoxin reductase 1 (Tr1). Analyses with purified proteins revealed that all three enzymes catalyzed doxorubicin-dependent NADPH oxidation, but only Cbr1 and Cbr3 catalyzed doxorubicinol formation. Doxorubicin-dependent NADPH oxidation by Tr1 was likely due to redox cycling. Subcellular fractionation results showed that doxorubicin-dependent redox cycling activity was primarily microsomal, whereas doxorubicinol-forming activity was exclusively cytosolic, as were all three enzymes. An immunoclearing approach was used to assess the contributions of the three enzymes to doxorubicinol formation in the complex milieu of the cytosol. Immunoclearing Cbr1 eliminated 25% of the total doxorubicinol-forming activity in cytosol, but immunoclearing Cbr3 had no effect, even in Tr1 null livers that overexpressed Cbr3.

The immunoclearing results constituted strong evidence that Cbr1 contributed to doxorubicinol formation in mouse liver but that enzymes other than Cbr1 also played a role, a conclusion supported by ammonium sulfate fractionation results, which showed that doxorubicinol-forming activity was found in fractions that contained little Cbr1. In conclusion, the results show that Cbr1 accounts for 25% of the doxorubicinol-forming activity in mouse liver cytosol but that the majority of the doxorubicinol-forming activity remains unidentified.

SIGNIFICANCE STATEMENT

Earlier studies suggested carbonyl reductase (Cbr) 1 plays a dominant role in converting chemotherapeutic doxorubicin to cardiotoxic doxorubicinol, but a new immunoclearing approach described herein shows that Cbr1 accounts for only 25% of the doxorubicinol-forming activity in mouse liver cytosol, that two other candidate enzymes—Cbr3 and thioredoxin reductase 1—play no role, and that the majority of the activity remains unidentified. Thus, targeting Cbr1 is necessary but not sufficient to eliminate doxorubicinol-associated cardiotoxicity; identification of the additional doxorubicinol-forming activity is an important next challenge.

Introduction

Doxorubicin (Dox), also known as Adriamycin, is used to treat a wide array of cancers, but its effectiveness is limited by dose-dependent cardiotoxicity, which manifests as congestive heart failure (Singal and Iliskovic, 1998; Swain et al., 2003; Kremer and Caron, 2004). The mechanism underlying cardiotoxicity is not fully understood, but doxorubicinol (Doxol), a metabolite generated by reduction of Dox at the C-13 carbonyl position (Fig. 1A) (Joerger et al., 2005) likely plays a significant role, as Doxol is far more potent than Dox in inhibiting several cardiac ion transporters (Boucek et al., 1987; Olson et al., 1988; Dodd et al., 1993; Hanna et al., 2014), and Doxol causes systolic and diastolic dysfunction in isolated rabbit heart muscle (Boucek et al., 1987; Olson et al., 1988).

ABBREVIATIONS: 11 β -HSD1, 11 β -hydroxysteroid dehydrogenase 1; Akr, aldo-keto reductase; Cbr, carbonyl reductase; Dox, doxorubicin; Doxol, doxorubicinol; Gclm, γ -glutamyl-cysteine ligase modulatory subunit; hydroxy-PP-Me, 3-(7-isopropyl-4-(methylamino)-7H-pyrrolo[2,3-d]pyrimidin-5yl)phenol; LC-MS/MS, liquid chromatography–mass spectrometry/collision-induced dissociation mass spectrometry; NFDm, nonfat dried milk; Tr1, thioredoxin reductase 1; Trx1, thioredoxin1.

Fig. 1. Reduction of Dox to its cardiotoxic metabolite Doxol. (A) Diagram showing the formation of Doxol via the two-electron reduction of the C-13 carbonyl group of Dox to an alcohol (arrows). (B) Dox-dependent NADPH oxidation by purified Cbr1, Cbr3, and Tr1. Reaction conditions were 200 μ M NADPH, indicated concentrations of Dox, and 1 μ M Cbr1, 1.9 μ M Cbr3, or 1.9 μ M Tr1 (Cbr3 and Tr1 histograms were normalized to 1 μ M enzyme). Change in A_{340} was monitored for 1 hour at 37°C, and the rate of NADPH oxidation was calculated from the linear phase of the time course. (C) NADPH-dependent Doxol formation by purified Cbr1, Cbr3, and Tr1. Reaction conditions were 200 μ M NADPH, 200 μ M Dox, and 1 μ M enzyme; incubations were for 1 hour at 37°C. Doxol levels were measured by LC-MS/MS. Error bars represent 1 S.D.; $n = 3$ for all reactions; * $P < 0.05$ by Student's t test.

Compared with its parent compound, Doxol displays minimal antineoplastic activity (Olson et al., 1988; Chang et al., 1989; Bernardini et al., 1991; Heibein et al., 2012). This is critical, as it suggests that the antitumor properties of Dox are not inherently linked to its cardiotoxicity. Preventing the metabolism of Dox to Doxol could thus increase the safety of the drug while retaining its effectiveness. As such, the goal of this study was to directly assess the contributions of three cytosolic enzymes to Doxol formation in liver, the most dominant location of xenobiotic metabolism. The enzymes carbonyl reductase (Cbr) 1, Cbr3, and thioredoxin reductase 1 (Tr1) were selected for the following reasons.

Cbr1 can catalyze the NADPH-dependent reduction of Dox to Doxol in vitro, and drugs that inhibit purified Cbr1 activity also inhibit Doxol formation by liver cytosol (Kassner et al., 2008; Bains et al., 2010), suggesting Cbr1 is the predominant Dox reductase in liver cytosol. Genetic evidence also suggests Cbr1 plays a major role in Doxol formation. Mice with a single null allele of Cbr1 show decreased sensitivity to Dox-induced cardiotoxicity, whereas mice that overexpress Cbr1 show increased sensitivity (Forrest et al., 2000; Olson et al., 2003). Additionally, cancer cell lines that overexpress carbonyl reductase are resistant to the antiproliferative effects of Dox (Bains et al., 2013). Pharmacological and genetic studies alone, however, do not confirm a major role for Cbr1 in Doxol formation, as drugs are often nonspecific and genetic interventions often have secondary effects on gene expression.

Cbr3 is a syntenic homolog of Cbr1. Although less well studied, it has also been shown to catalyze Doxol formation in vitro (Blanco et al., 2008; Bains et al., 2010). In vivo evidence for Cbr3 playing a role in Doxol formation derives from work done on knockout mice missing the

γ -glutamyl-cysteine ligase modulatory subunit (*Gclm*) gene encoding the glutamate-cysteine ligase modifier subunit. These mice overexpress Cbr3 mRNA, and to a lesser extent Cbr1 mRNA (Haque et al., 2010), and show elevated formation of Doxol by liver cytosol and isolated hepatocytes (Schaupp et al., 2015).

Tr1 is known to reduce many substrates besides thioredoxin, including the small molecules lipoate (Arnér et al., 1996), lipid hydroperoxides (Björnstedt et al., 1995), dehydroascorbate (May et al., 1997), and menadione (Luthman and Holmgren, 1982). Liver-specific deletion of the thioredoxin reductase 1 (*Txnrd1*) gene encoding Tr1 also causes massive overexpression of Cbr3 (Bondareva et al., 2007; Suvorova et al., 2009), potentially as a compensatory response to the loss of Tr1. Because of its broad substrate specificity, as well as a potential substrate overlap with Cbr3, we evaluated Tr1 as another candidate for playing a role in Doxol formation.

The aldo-keto reductase (AKR) 1C3 can catalyze Doxol formation in vitro; however, we did not include it in our investigations because the inhibition profile of AKR1C3 does not match that of liver cytosol (Tanaka et al., 2005; Kassner et al., 2008).

Initially, purified recombinant enzymes were tested for their ability to catalyze Dox-dependent NADPH oxidation and NADPH-dependent Doxol formation in vitro. Although all three enzymes catalyzed Dox-dependent NADPH oxidation, only Cbr1 and Cbr3 catalyzed Doxol formation. Instead of Doxol formation, Tr1 catalyzed Dox-dependent generation of H_2O_2 , probably via redox cycling. To directly test for a physiologic role of the three enzymes in Dox metabolism, antibodies to the three proteins were developed and used to immunoclear the respective proteins from liver cytosol. Immunoclearing Cbr3 or Tr1 had no effect on Doxol formation by liver cytosol, suggesting these enzymes

played no physiologic role in Doxol formation. In contrast, immunoclearing Cbr1 eliminated 25% of the Doxol-forming activity, verifying that Cbr1 contributes to Doxol formation in vivo. Importantly, however, the results also showed that most of the Doxol-forming activity in liver cytosol was not Cbr1.

Materials and Methods

Mouse Liver Fractionation. Mice were handled using procedures approved by Oregon State University Institutional Animal Care and Use Committee. All mice were strain C57Bl6. A mixture of male and female mice between 3 and 9 months of age were used. No sex- or age-specific trends in the results obtained were observed. The $\Delta Gclm$ knockout line and liver-specific $\Delta Txnrd1$ knockout line were described previously (Bondareva et al., 2007; Haque et al., 2010). Mice were fasted overnight to minimize variability caused by recent feeding activity and euthanized by cervical dislocation. Livers were perfused in situ with PBS (150 mM NaCl, 50 mM NaPO₄ pH 7.4) to reduce blood content, removed to a petri dish, minced, and homogenized (Elvehjem, five strokes) in 10 volumes cold MOPS isolation buffer (200 mM sucrose, 10 mM Tris/4-morpholinepropanesulfonic acid pH 7.4, 1 mM EGTA) (Frezza et al., 2007). Homogenates were centrifuged for 10 minutes at 12,000g to remove nuclei and undisrupted cells. Clarified lysates were centrifuged for 30 minutes at 45,000g to remove mitochondria. The 45,000g supernatants were centrifuged for 1 hour at 100,000g to obtain microsomes (100,000g pellet) and cytosols (100,000g supernatant). Microsomes were resuspended in MOPS isolation buffer. Protein concentrations were determined by the Bradford method using bovine serum albumin as standard.

Ammonium sulfate fractionation was initiated by adding solid (NH₄)₂SO₄ to cytosol prepared from 13 pooled mouse livers to achieve a salt solution at 40% of saturation (1.64 M). After stirring 30 minutes at 4°C, the mixture was centrifuged for 30 minutes at 12,000g to obtain a 40% pellet and 40% supernatant. Solid (NH₄)₂SO₄ was added to the 40% supernatant, and the above steps were repeated to achieve first a 50% pellet and supernatant and subsequently a 60% pellet and supernatant. Precipitates were resuspended in 150 mM KCl, 50 mM KPO₄ pH 7.4. Fractions were stored at -20°C until assay.

Protein Expression and Purification. Using cDNA plasmids purchased from Open Biosystems (Huntsville, AL) as templates, polymerase chain reaction fragments containing the complete coding regions of mouse Cbr1, Cbr3, and Tr1 and a synthetic NdeI site overlapping the start codon were blunt end-cloned into EcoR5-cleaved pBluescript KS and subcloned as NdeI/Hind3 fragments into the expression vector pET28a (Novagen, La Jolla, CA) such that expressed proteins had a histidine tag and thrombin cleavage site at the N terminus and the native amino acid at the C terminus. BL21 bacteria transformed with the expression plasmids were shaken at 37°C in LB medium containing 50 µg/ml kanamycin. When absorbance at 600 nm (A_{600}) reached 0.6, 1 mM isopropyl- β -D-thiogalactoside was added to induce protein expression, and incubation continued for 6 hours at 25°C or overnight at 18°C. Cells were harvested by centrifugation at 3300g, resuspended in 20 ml chilled extraction buffer (150 mM NaCl, 50 mM NaPO₄ pH 7.4), and lysed using an M-110P Microfluidizer (Microfluidics, Westwood, MA). Lysates were clarified by centrifugation at 15,000 rpm for 30 minutes in a Sorvall SS-34 rotor. Clarified lysate was mixed with 1 ml TALON metal affinity resin (Clontech, Mountain View, CA), and the mixture incubated for 1 hour with tumbling at 4°C. Resin containing bound protein was collected by centrifugation for 1 minute at 2000g, washed four times with 40 ml chilled extraction buffer, transferred to a gravity column, and washed with 10 ml extraction buffer and 5 ml of extraction buffer with 5 mM imidazole. Bound protein was eluted in 500-µl increments using 5 ml elution buffer (extraction buffer with 50 mM imidazole). Protein concentration was determined by A_{280} using extinction coefficients of 20,970 M⁻¹cm⁻¹ for Cbr1 and Cbr3 and 58,330 M⁻¹cm⁻¹ for Tr1. Protein purity, assessed by SDS-PAGE and Coomassie staining, was greater than 95%; thus no further purification was required. Gels representative of the purity achieved are shown in Supplemental Material (Supplemental Fig. 1). Proteins were stored at 4°C in elution buffer containing 0.1 mM dithiothreitol. Freeze/thawing or storage at concentrations above 25 µM led to protein precipitation and was avoided. When precipitation occurred, fresh preparations of enzyme were made.

Coupling of Cbr1 and Cbr3 to Affi-gel 15 and Tr1 to Affi-gel 10 was done using the aqueous protocol described by the vendor (Bio-Rad, Hercules, CA).

Prior to coupling, imidazole and dithiothreitol were removed by gel filtration using 150 mM KCl, 50 mM KPO₄ pH 8.0 as exchange buffer.

Immunologic Procedures. Antisera were generated in New Zealand White rabbits, using full-length mouse Cbr1, Cbr3, and Tr1 protein with N-terminal histidine tags as antigen, expressed and purified as described above. Cbr3 and Tr1 immunizations and bleeds were done at the Oregon State University Laboratory Animal Resources Center. Cbr1 immunizations and bleeds were done by Pacific Immunology (Ramona, CA). Two rabbits were used for each protein. Antisera identification codes were assigned based on the source rabbit (Cbr1, 12081 and 12082; Cbr3, OB2 and OB4; Tr1, OB1 and OB3). Terminal bleeds (100–120 ml) were done by heart puncture. Raw antisera were prepared by allowing blood to coagulate at 4°C overnight, centrifuging the mixture at 5000g for 15 minutes, and storing 10-ml aliquots of supernatant at -70°C. Woring aliquots were stored at 4°C, with 0.1% NaN₃ added as a preservative.

Raw Cbr3 antiserum cross-reacted with Cbr1 and raw Cbr1 antiserum cross-reacted with Cbr3 when used to probe immunoblots. To increase specificity, raw Cbr1 antiserum (12081) was cross-adsorbed to Cbr3-conjugated Affi-gel 15 (Bio-Rad) to obtain Cbr1-specific antiserum, and raw Cbr3 antiserum (OB4) was cross-adsorbed to Cbr1-conjugated Affi-gel to obtain Cbr3-specific antiserum. Comparison of immunoblots probed with raw Cbr3 antiserum, Cbr3-specific antiserum, and Cbr1-specific antiserum showed that Cbr1 and Cbr3 migrated as a triplet during SDS-PAGE analysis of mouse liver cytosol, with the slower two bands representing Cbr1 and the faster band representing Cbr3.

To remove bulk immunoglobulins that would compete for Protein A binding during immunoclearing, Cbr1- and Cbr3-specific antisera were affinity-purified. Briefly, 10 ml of specific antisera were incubated with 5 ml of Cbr1-conjugated or Cbr3-conjugated Affi-gel 15 beads overnight at 4°C, the beads were rinsed several times with PBS, and bound antibodies were eluted with 150 mM NaCl, 20 mM HCl into tubes containing 100 µl of neutralizing 1 M KPO₄ pH 7.5 per 1.5 ml of eluate.

Immunoclearing of Cbr1 or Cbr3 was done using a noncovalent bridge of affinity-purified Cbr1-specific or Cbr3-specific antibody bound to Protein A magnetic beads (Bio-Rad). Beads were preincubated overnight with antibodies and washed several times with PBS immediately before use. Beads preincubated only with PBS were used for mock-cleared controls. About 50 µl of washed beads was used to clear Cbr1 or Cbr3 from 120 µg of cytosolic liver protein.

Immunoclearing of Tr1 was done using affinity-purified anti-Tr1 antibody that was covalently coupled to Affi-gel 10. Covalent coupling was necessary because the molecular weights of Tr1 and IgG heavy chain are similar (50 kDa) and unavoidable leaching of some IgG using the noncovalent Protein A bridge method would complicate interpretation of immunoblots designed to measure the efficiency of Tr1 removal. Ethanolamine-coupled Affi-gel was used for mock-cleared controls. About 50 µl of anti-Tr1-coupled Affi-gel was used to clear Tr1 from 300 µg of cytosolic liver protein.

After the efficiency of immunoclearing was determined by immunoblotting, 12-µg equivalents of immunocleared or mock-cleared cytosolic protein were assayed for Dox-dependent NADPH oxidation activity and NADPH-dependent Doxol forming activity as described below.

For immunoblot analyses, proteins were separated by SDS-PAGE and electroblotted to nitrocellulose membrane (Bio-Rad). Membranes were blocked overnight at 4°C in TBST (20 mM Tris pH 7.4, 150 mM NaCl, 0.1% Tween) containing 5% nonfat dried milk (NFDm). Primary antibody incubations were for at least 2 hours at 25°C, using a 1:1000 dilution of raw antiserum or 1:300 dilution of affinity-purified antibody in TBST 5% NFDm. After four 5-minute washes with TBST 5% NFDm, blots were incubated with secondary antibody for at least 1 hour at 25°C, using a 1:5000 dilution of goat anti-rabbit horseradish peroxidase-conjugated IgG (Bio-Rad). Following four TBST washes, blots were developed with Western Lightning enhanced chemiluminescent substrate (Santa Cruz Biotechnology, Dallas, TX) and imaged using a ChemiGenius Bio-imaging system (Syngene, Frederick, MD). Protein band intensities were determined using Syngene Genetools software.

Enzyme Assays. Dox-dependent NADPH oxidation was measured in UV-transparent 96-well plates by tracking A_{340} using a Biotek Synergy 2 Multi-Mode Microplate Reader (Winooski, VT). Reaction cocktails contained 50 mM KPO₄ pH 7, 0–200 µM Dox, 1–2 µM recombinant enzyme or 50–100 µg of liver protein, and 200 µM NADPH (added last) in a total volume of 150 µl. Absorbance was monitored for 1 hour at 37°C, and the molar amount of NADPH

TABLE 1
Kinetic parameters K_m , k_{cat} , and k_{cat}/K_m for Dox-dependent NADPH oxidation by purified Cbr1, Cbr3, and Tr1

Enzyme	R^2	Parameter		
		K_m	k_{cat}	k_{cat}/K_m
		μM	$\text{s}^{-1} \times 10^{-3}$	$\mu\text{M}^{-1} \text{s}^{-1} \times 10^{-6}$

Tr1	0.969	36	10	290

oxidized was calculated using an extinction coefficient of $6220 \text{ M}^{-1}\text{cm}^{-1}$ and estimated pathlength of 3 mm. The rate of NADPH oxidation in the absence of Dox was subtracted from rates measured in the presence of Dox.

NADPH-dependent Doxol formation was measured by liquid chromatography–mass spectrometry/collision-induced dissociation mass spectrometry (LC-MS/MS). Reaction cocktails were prepared as described above. After a 1-hour incubation at 37°C , reactions were stopped and proteins precipitated by adding chilled sulfosalicylic acid to 0.5%. Precipitated protein was removed by centrifugation for 10 minutes at 12,000g. Supernatants were analyzed using a SCIEX 3200 Q TRAP LC-MS/MS system equipped with Shimadzu LC-20AD pumps, SIL-20A model autosampler, CTO-10ASvp model column oven, and CBM-20A model system controller. Dox was separated from Doxol using an Agilent Poroshell 120 PFP reversed-phase column (Santa Clara, CA), 10 μl sample injection volume, 0.3 ml/min flow rate, and 10%–90% acetonitrile gradient applied over 10 minutes. For Dox, the Q1 parent peak was 544.4 Da, and the Q3 peaks were 397.3, 379.3, and 130.1 Da. For Doxol, the Q1 parent peak was 546.4 Da, and Q3 peaks were 399.3, 381.3, and 130.1 Da. The 399.3 peak was used for quantitation of Doxol, and the other peaks were used as quality controls. Representative mass spectra are shown in Supplemental Material (Supplemental Fig. 2).

Kinetic parameters were calculated using nonlinear least squares regression. For mouse liver cytosol, V_{max} was calculated instead of the catalytic constant (k_{cat}). Raw data are provided in Supplemental Material (Supplemental Table 1).

H_2O_2 formation was measured using an Amplex red-based assay kit (Invitrogen, Carlsbad, CA). Purified Cbr1 and Tr1 (1 μM) were mixed with 50 μM Dox in 50 mM KPO_4 pH 7.4. NADPH (200 μM) was added to initiate the reaction and bring the final volume to 100 μl . Samples were combined with 100 μl of Amplex red working solution (100 μM Amplex red, 200 U/ml horseradish peroxidase, 50 mM KPO_4 pH 7.4). Using a Qubit 3.0 fluorometer (Thermo Fisher Scientific, Waltham, MA), samples were excited at 470 nm, and emission in the far-red range (665–720 nm) was tracked. A standard curve of 0 to 1 mM H_2O_2 was used to quantify H_2O_2 production by samples. The same procedure was followed to measure H_2O_2 production by 30 μg of liver cytosolic or microsomal protein.

Results

Dox-Dependent NADPH Oxidation and NADPH-Dependent Doxol Formation by Purified Cbr1, Cbr3, and Tr1. As described above, the enzymes Cbr1, Cbr3, and Tr1 were potential candidates for catalyzing reduction of Dox to Doxol (Fig. 1A). As an initial assessment of these candidate enzymes, recombinant mouse Cbr1, Cbr3, and Tr1 were purified and tested for their ability to catalyze Dox-dependent NADPH oxidation. All three enzymes were active (Fig. 1B). Kinetic

parameters for Dox-dependent NADPH oxidation by these enzymes were determined and are summarized in Table 1. Cbr1 had a k_{cat} 10-fold greater than Cbr3 and 1.5-fold greater than Tr1. Tr1 had the highest catalytic efficiency (k_{cat}/K_m).

Although spectrophotometric analysis of NADPH oxidation was an expedient way of assessing whether an oxidoreductase used Dox as a substrate, it did not establish that the product of the reaction was Doxol. For example, ring keto groups on Dox could alternatively serve as electron acceptors. We thus used LC-MS/MS to directly measure the production of Doxol by Cbr1, Cbr3, and Tr1. Pilot analyses with standards established that Doxol could be distinguished from its precursor and that the Doxol mass/charge (M/Z) peaks were proportional to the amount of Doxol added to the mixture (Supplemental Fig. 2). Using the LC-MS/MS assay, the amount of Doxol formed by each enzyme during a 1-hour incubation with 200 μM NADPH and Dox was determined (Fig. 1C). Both Cbr1 and Cbr3 produced Doxol. In contrast, despite showing a high rate of Dox-dependent NADPH oxidation, Tr1 produced no Doxol during the reaction. Thus, tracking Dox-dependent NADPH oxidation alone was not sufficient to draw conclusions regarding the formation of Doxol. Kinetic parameters for Doxol formation by Cbr1 and Cbr3 were determined and compared with kinetic parameters for Doxol formation by mouse liver cytosol (Table 2). Cbr1 and Cbr3 had similar K_m values (99 and 74 μM , respectively), but the catalytic efficiency (k_{cat}/K_m) for Doxol formation by Cbr1 was 280-fold higher than by Cbr3. Importantly, the K_m values for Doxol formation exhibited by purified Cbr1 and Cbr3 were similar to those exhibited by liver cytosol (75 μM), consistent with these enzymes playing a role in vivo.

Doxorubicin-Dependent Redox Cycling Catalyzed by Tr1. Because Dox-dependent NADPH oxidation by Tr1 was not associated with Doxol formation, we investigated whether Tr1 was catalyzing NADPH oxidation by a redox cycling mechanism (Fig. 2A). In this model, an electron equivalent from NADPH is transferred to Dox to form a semiquinone but is subsequently transferred to another entity, presumably solvent oxygen, which results in regeneration of Dox and the sequential formation of superoxide radical and H_2O_2 . To test this hypothesis, Tr1 and Cbr1 were incubated with Dox and NADPH, and the amount of H_2O_2 produced over the course of the reaction was measured using Amplex Red reactivity as an indicator. The results (Fig. 2B) showed that in the presence of Dox and NADPH, Tr1

(B) H₂O₂ formation by Cbr1 and Tr1. Reaction conditions were 200 μM NADPH, 50 μM Dox, and 1 μM enzyme; incubations were for 1 hour at room temperature.

generated significant amounts of H₂O₂. Cbr1 also produced H₂O₂, but at a much slower rate. The efficient formation of H₂O₂, along with the lack of Doxol formation, suggested Tr1 was indeed catalyzing Dox-dependent redox cycling.

Subcellular Localization of Dox-Metabolizing Activities in Liver.

To confirm the cytosolic localization of Cbr1, Cbr3, and Tr1 and to determine whether the enzymes catalyzing Dox-dependent NADPH oxidation and Doxol formation were similarly cytosolic, 45,000g liver supernatants were fractionated into their microsomal and cytosolic components by centrifugation at 100,000g. Equal amounts of protein from each component were analyzed for Cbr1, Cbr3, and Tr1 protein by immunoblotting, Dox-dependent NADPH oxidation by spectrophotometry, and Doxol-forming activity by LC-MS/MS. Immunoblot analyses (Fig. 3A) confirmed that all three proteins were primarily cytosolic. However, when Dox-dependent NADPH oxidation activity was assayed, most of the activity present in the original 45,000g supernatant was recovered in the microsomal fraction, and only 30% of the activity was recovered in the cytosolic fraction (Fig. 3B). In contrast, when Doxol formation was assayed, almost all of the activity present in the 45,000g supernatant was recovered in the cytosolic fraction (Fig. 3C). To test whether the high levels of Dox-dependent NADPH oxidation activity observed in microsomal fractions was due to redox cycling, we measured the production of H₂O₂ by cytosolic and microsomal fractions. As shown in Fig. 3D, microsomal fractions produced significant amounts of H₂O₂, whereas cytosolic fractions did not, suggesting that Dox-dependent redox cycling was occurring in the microsomes.

Effect of Immunoclearing Cbr1 on Doxol-Forming Activity in Mouse Liver Cytosol. As demonstrated above, purified Cbr1 and Cbr3 were able to catalyze NADPH-dependent Doxol formation, with Cbr1 catalyzing the reaction much more efficiently than Cbr3. However,

these *in vitro* analyses did not establish the extent to which these enzymes contributed to Doxol formation in the complicated milieu of the cytosol. Posttranslational modifications, accessory proteins, and small molecule effectors could impact the formation of Doxol by these enzymes *in vivo*. Additionally, other Doxol-forming enzymes might exist in the cytosol, diluting the contributions of Cbr1 and Cbr3 to overall activity. Genetic or drug interventions are often used to study the role of specific proteins within an organism or cell; however, genetic interventions often have unpredictable effects on the transcriptome, and “specific” drugs often target many enzymes in addition to the one being studied. We thus developed an immunoclearing approach to analyze the roles of Cbr1, Cbr3, and Tr1 in Doxol formation. This approach avoids complications that could arise from genetic or drug interventions while still requiring the enzymes to function within the context of the cytosol.

Protein A magnetic beads preincubated with Cbr1-specific antibody were used to immunoclear Cbr1 from six mouse liver cytosols. Beads preincubated only with buffer served as mock-cleared controls. The amount of Cbr1 present in Cbr1-cleared and mock-cleared cytosols was determined by immunoblot analysis (Fig. 4A). Densitometry showed that on average 67% of Cbr1 was cleared. To confirm the specificity of the immunoclearing reaction, immunoblots were reprobed with antibody against the small redox protein thioredoxin (Trx1). As expected, there was no significant difference in the amount of Trx1 present in Cbr1-cleared and mock-cleared cytosols (Fig. 4A).

Equivalent amounts of Cbr1-cleared and mock-cleared cytosolic protein were incubated with NADPH and Dox, and the amount of Doxol produced during a 1-hour reaction was measured by LC-MS/MS (Fig. 4B). Five of six cytosols showed a statistically significant reduction in the amount of Doxol produced by Cbr1-cleared cytosol, compared with mock-cleared cytosol. When averaged, Doxol formation by the Cbr1-cleared cytosols was 21% lower than by the mock-cleared

Fig. 3. Subcellular localization of Cbr1, Cbr3, and Tr1 protein; Dox-dependent NADPH oxidation activity; NADPH-dependent Doxol-forming activity; and Dox-dependent H_2O_2 -forming activity in mouse liver. (A) Immunoblot analysis of Cbr1, Cbr3, and Tr1 protein in indicated supernatants (S) and pellets (P): 45,000g S (a mixture of cytosol and microsomes), 100,000g S (cytosol), and 100,000g P (microsomes). $\Delta Gclm$ lysates were used to facilitate Cbr3 localization. (B) Dox-dependent NADPH oxidation by indicated fractions of wild-type liver lysates. Reaction conditions were 200 μM NADPH, 200 μM Dox, and 50 μg fraction protein; incubations were for 1 hour at 37°C . (C) NADPH-dependent Doxol formation by indicated fractions of wild-type liver lysates. Reaction conditions and incubations were as described in (B). Doxol levels were measured by LC-MS/MS. (D) H_2O_2 formation by indicated fractions of wild-type liver lysates. Reaction conditions were 200 μM NADPH, 50 μM Dox, and 30 μg fraction protein; incubations were for 1 hour at 25°C . Error bars represent 1 S.D.; $n = 3$ for all reactions; * $P < 0.05$ by Student's t test.

group (Fig. 4C). Because the immunoblotting analyses showed that the immunoclearing procedure removed only 67% of the Cbr1 in the cytosol, we calculated that 31% of the Doxol-forming activity in mouse liver cytosol was attributable to Cbr1. When the immunoclearing

analyses were repeated using the same cytosols and independently prepared new cytosols ($n = 12$), slightly different estimates for the amount of activity attributable to Cbr1 were obtained, ranging from an average of 20% to 31%. From all experiments, we calculated that on average $23.4\% \pm 13.7\%$ of Doxol-forming activity (roughly 25%) was attributable to Cbr1. The immunoclearing results thus provided unequivocal evidence that Cbr1 contributed significantly to Doxol formation in liver. Importantly, however, even with the majority of Cbr1 cleared from the cytosol, most of the Doxol-forming activity remained.

Effect of Immunoclearing Cbr3 and Tr1 on Dox-Dependent NADPH Oxidation and Doxol-Forming Activity in Mouse Liver Cytosol. The above results showed that Cbr1 accounted for about 25% of the total Doxol-forming activity in liver cytosol. To investigate whether Cbr3 and Tr1 contributed to Dox metabolism, these proteins were also selectively immunocleared from mouse liver cytosol. Immunoblot analyses showed that Cbr3 and Tr1 were efficiently removed by the immunoclearing procedure (Fig. 5A). Despite near total clearing of Cbr3, the levels of Doxol-forming activity were unaffected (Fig. 5, B and C). Thus, Cbr3 did not contribute to the Doxol-forming activity detected in liver cytosol. Dox-dependent NADPH oxidation activity was also measured in Tr1-cleared and mock-cleared samples, and no significant difference was observed (Fig. 5, D and E). Thus, although purified Tr1 efficiently catalyzed Dox-dependent NADPH oxidation in vitro, Tr1 did not contribute to Dox-dependent NADPH oxidation in the context of the cytosol.

Doxol Formation in $\Delta Tnxrd1$ Mouse Liver Cytosol. Cbr3 was implicated as a potential Dox reductase when it was observed that $\Delta Gclm$ null mice, which have elevated levels of Cbr3 mRNA and protein, have higher rates of Doxol formation (Schaupp et al., 2015). Interestingly, liver-specific deletion of the *Tnxrd1* gene also resulted in greatly elevated levels of Cbr3 and mildly elevated levels of Cbr1 (Fig. 6A). We investigated whether Cbr3 contributed significantly to Doxol formation in tissues that overexpressed Cbr3. We found that $\Delta Tnxrd1$ cytosols produced significantly more Doxol, but the effect was small (35% increase), relative to the large increase in Cbr3 protein (Fig. 6A).

To ascertain whether the increased Doxol-forming activity observed in $\Delta Tnxrd1$ null cytosols was attributable to Cbr3, Cbr1, or both enzymes, we immunocleared Cbr3 and Cbr1 individually and simultaneously from four $\Delta Tnxrd1$ cytosols (Fig. 6C). Total clearing of Cbr3 was achieved in all cytosols, whereas clearing of Cbr1 was less thorough (on average, about 55%). Clearing Cbr3 had no effect on Doxol formation, whereas clearing Cbr1 again led to a reduction in Doxol formation. Clearing Cbr1 and Cbr3 simultaneously did not lead to any difference in Doxol formation when compared with clearing Cbr1 alone (Fig. 6D). This suggests that even when Cbr3 was highly overexpressed, it was not responsible for any of the observed Doxol-forming activity in liver cytosol. The increased Doxol formation observed in $\Delta Tnxrd1$ livers was thus likely due to the small increase in Cbr1 or some as yet unidentified enzyme.

Ammonium Sulfate Fractionation of Doxol-Forming Activity in Liver Cytosol. Having shown that only 25% of the Doxol-forming activity in liver cytosol was attributable to Cbr1, most of the total Doxol-forming activity remained unidentified. As an initial means of characterizing this remaining activity, we fractionated liver cytosol by ammonium sulfate precipitation. SDS-PAGE analysis revealed that each fraction had a distinct protein profile (Fig. 7A). Immunoblot analysis revealed that Cbr1 was found primarily in the 60% supernatant (Fig. 7B), whereas Doxol-forming activity was found primarily in the 60% pellet and 50% pellet (Fig. 7C). The finding that peak Doxol-forming activity was found in an ammonium sulfate fraction containing relatively little Cbr1 independently corroborated the conclusion of the immunoclearing

Fig. 4. Immunoclearing of Cbr1 and its effect on Doxol-forming activity in mouse liver cytosol. (A) Immunoblot analyses of Cbr1 in mock-cleared (–) and Cbr1-cleared (+) cytosols from six wild-type (wt) mice. Cbr1 protein levels were determined by densitometry, and the % Cbr1 protein remaining after immunoclearing, relative to mock-cleared samples, is shown at bottom. Trx1 levels were determined in parallel as a control. (B) NADPH-dependent Doxol-forming activity in mock-cleared and Cbr1-cleared cytosols. Reaction conditions were 200 μ M NADPH, 200 μ M Dox, and 12- μ g equivalents of cytosolic protein; incubations were for 1 hour at 37°C. Doxol levels were measured by LC-MS/MS. The % Doxol-forming activity remaining after immunoclearing, relative to mock-cleared samples, is shown at bottom. Error bars represent 1 S.D.; $n = 3$ technical replicates for all reactions; * $P < 0.05$ by Student's t test. (C) Mock-cleared and Cbr1-cleared Doxol-forming activity for the six biologic replicates. The concentration of Doxol generated is reported in arbitrary units (AU), where the average level in mock-cleared samples is set to 1. Error bars represent 1 S.D.; * $P < 0.005$ by Student's t test.

experiment that enzymes other than Cbr1 comprised the majority of the Doxol-forming activity in liver cytosol.

Discussion

Although several purified enzymes have been shown to catalyze Dox reduction, past efforts to test the biologic relevance of such findings have relied exclusively on pharmacological and genetic approaches. However, these approaches share the fundamental weakness of non-specificity. Enzyme inhibitors rarely are specific for only one enzyme, and altering the genome for the purpose of over- or underexpressing a specific gene often has unpredictable effects on the expression of other genes. To avoid these issues, we developed a method of studying Doxol formation that takes advantage of the truly specific binding between

antigen and antibody. We raised antibodies against Cbr1, the most studied Dox reductase, and against Cbr3 and Tr1, two other enzymes potentially involved in Dox reduction, and used the antibodies to immunoclear the respective proteins from mouse liver cytosol. By selectively removing each of these specific enzymes, we were able to quantify the contribution of each enzyme to Dox metabolism in the quasi in vivo context of liver cytosol.

Our initial characterization of the three enzymes revealed that Cbr3 and Cbr1 were both capable of producing Doxol but that Tr1 was not, despite efficiently catalyzing Dox-dependent NADPH oxidation. Further analyses revealed that purified Tr1 catalyzed Dox-dependent redox cycling, generating significant amounts of H_2O_2 . However, subcellular fractionation analyses showed that Dox-dependent redox cycling activity in liver lysates was primarily microsomal, whereas Tr1 protein

Fig. 5. Immunoclearing Cbr3 and Tr1 from mouse liver cytosols and effect on Dox-dependent NADPH oxidation and NADPH-dependent Doxol formation. (A) Immunoblot analysis of Cbr3 and Tr1 in mock-cleared (–) and immunocleared (+) mouse liver cytosols. The Cbr3 immunoblots were probed with either raw anti-Cbr3 antiserum (top) or Cbr3-specific antiserum (bottom). (B) NADPH-dependent Doxol formation by mock-cleared and Cbr3-cleared cytosols. Reaction conditions were 200 μM NADPH, 200 μM Dox, and 45- μg equivalents of cytosolic protein; incubations were for 1 hour at 37°C. Doxol levels were measured by LC-MS/MS. Triplicate incubations for each cytosol were pooled and analyzed as one sample. (C) Mock-cleared and Cbr3-cleared Doxol-forming activity for the three biologic replicates. The concentration of Doxol generated is reported in arbitrary units (AU), where the average level in mock-cleared samples is set to 1. Error bars represent 1 S.D.; there was no significant difference. (D) Dox-dependent NADPH oxidation by mock-cleared and Tr1-cleared cytosols. Reaction conditions were as described in (B). Error bars represent 1 S.D.; $n = 3$ technical replicates for all reactions. (E) Mock-cleared and Tr1-cleared Dox-dependent NADPH oxidation for the three biologic replicates. The change in NADPH is reported in arbitrary units (AU), where the average change in mock-cleared samples is set to 1. Error bars represent 1 S.D.; there was no significant difference.

was almost exclusively cytosolic. Furthermore, immunoclearing Tr1 from cytosol had no effect on the observed redox cycling activity. Tr1 was thus not a significant contributor to the Dox-dependent redox cycling activity observed in liver lysates. Identifying the Dox-dependent redox cycling activity is important because redox cycling may contribute to the chemotherapeutic and/or cardiotoxic activities of Dox. For example, Dox is known to intercalate into DNA, and if it were to participate in redox cycling reactions from that location, it could create localized high concentrations of DNA-damaging reactive oxygen species and thereby arrest replication.

When Cbr3 was immunocleared from liver cytosol, no reduction in Doxol-forming activity was observed, indicating that this enzyme did not contribute to Doxol formation by liver cytosol. In contrast, when Cbr1 was immunocleared from liver cytosol, 25% of the Doxol-forming activity was removed, indicating that 25% of the Doxol-forming activity in liver was attributable to the Cbr1 polypeptide. Importantly, 75% of the Doxol-forming activity in liver cytosol remained after Cbr1 was removed by immunoclearing, indicating that other enzymes constituted the majority of the Doxol-forming activity. This conclusion was further supported by ammonium sulfate fractionation results that showed that

peak levels of Doxol-forming activity were detected in fractions that contained little Cbr1.

Cbr3 mRNA is the most highly induced message in both ΔTxnrd1 null (Bondareva et al., 2007; Suvorova et al., 2009) and ΔGclm null tissues (Haque et al., 2010). We earlier suggested that Cbr3 played a role in Doxol formation based on the observations that cytosols from ΔGclm livers and isolated hepatocytes had elevated levels of Cbr3 protein and elevated levels of Doxol-forming activity, that ΔGclm hepatocytes incubated with Dox produced a substance toxic to myocytes and produced higher levels of Doxol, and that purified Cbr3 was able to reduce Dox to Doxol in vitro (Schaupp et al., 2015). Our current findings show that purified Cbr1 was 280-fold more efficient than Cbr3 in converting Dox to Doxol and that immunoclearing Cbr1, but not Cbr3, from either wild-type or ΔTxnrd1 cytosols removed a significant fraction of the measurable Doxol-forming activity. In view of the current findings, we suspect that the increase in Doxol-forming activity previously reported to occur in ΔGclm livers (Schaupp et al., 2015) was due to induction of Cbr1, rather than induction of Cbr3. Cbr1 is induced in both ΔGclm and ΔTxnrd1 livers, although not to the same extent as Cbr3.

Fig. 6. Immunoclearing of Cbr1 and/or Cbr3 and its effect on Doxol-forming activity in $\Delta Txnrd1$ liver cytosols that overexpress Cbr3. (A) Immunoblot analysis of Cbr3 and Cbr1 in wild-type (wt) and $\Delta Txnrd1$ mouse liver cytosols; 18 μ g of total cytosolic protein loaded per lane. The top panel shows a blot probed with Cbr3-specific antibody. The bottom panel shows the same blot reprobed with Cbr1-specific antibody; because the blot was not stripped, the fast-migrating Cbr3 signal remained visible. (B) NADPH-dependent Doxol formation by wild-type and $\Delta Txnrd1$ cytosols. Reaction conditions were 200 μ M NADPH, 200 μ M Dox, and 12- μ g equivalents of cytosolic protein; incubations were for 1 hour at 37°C. Doxol levels were measured by LC-MS/MS. (C) Immunoblot analysis of immunocleared $\Delta Txnrd1$ cytosols. Cbr1 and Cbr3 protein levels were determined by densitometry, and the % protein remaining after immunoclearing, relative to mock-cleared samples, is shown at bottom. (D) NADPH-dependent Doxol formation by mock-cleared, Cbr3-cleared, Cbr1-cleared, and Cbr3- and Cbr1-cleared $\Delta Txnrd1$ cytosols. Reaction conditions and incubations were as described in (B), except 50 μ M Dox was used. Doxol levels were measured by LC-MS/MS. The % Doxol-forming activity remaining after immunoclearing, relative to mock-cleared samples, is shown at bottom. Error bars represent 1 S.D.; $n = 4$ for all reactions; * $P < 0.05$ by Student's t test.

Olson et al. (2003) showed that mice systemically heterozygous for a $\Delta Cbr1$ deletion mutation are more resistant to the cardiotoxic effects of Dox. This result suggested that halving the amount of Cbr1 in the cytosol was cardioprotective. As our results indicated that only 25% of the total Doxol-forming activity in wild-type cytosol was attributable to Cbr1, heterozygosity for the $\Delta Cbr1$ null mutation would be expected to result in only a 12.5% reduction in total Doxol-forming activity. Thus, more experiments are necessary to understand the cardioprotective effect of $\Delta Cbr1$ heterozygosity during Dox treatment.

Others have shown (Jo et al., 2017) that coadministration of the Cbr1-inhibiting drug 3-(7-isopropyl-4-(methylamino)-7H-pyrrolo[2,3-d]pyrimidin-5-yl)phenol (hydroxy-PP-Me) during Dox treatment of rodents results in greater chemotherapeutic activity against implanted tumors and lower cardiotoxicity, and they concluded that Cbr1 plays a major role in converting Dox to cardiotoxic Doxol. Our current results are consistent with a role for Cbr1 in Doxol formation, but it is difficult to explain how inhibition of Cbr1 alone results in reduced cardiotoxicity when Cbr1 constitutes only 25% of the total Doxol-forming in liver cytosol. It is possible that Cbr1 constitutes a much higher percentage of total Doxol-forming activity in heart or other tissues, but we consider it more likely that the hydroxy-PP-Me is not specific for Cbr1 and instead inhibits a broader spectrum of NADPH-dependent oxidoreductases, including the unidentified enzymes responsible for 75% of the

Doxol-forming activity in liver cytosol. Nevertheless, the hydroxy-PP-Me study is extremely important because it suggests that development of drugs that inhibit Doxol-forming enzymes represents a promising strategy for combating cardiotoxicity during Dox chemotherapy.

Identification of the enzyme or enzymes that constitute the remaining unidentified Doxol-forming activity is important. Another enzyme capable of catalyzing Doxol formation in vitro is Akr1C3 (Kassner et al., 2008). However, the Doxol-forming activity of Akr1C3 is 10-fold more sensitive to the inhibitor 4-amino-1-tert-butyl-3-(2-hydroxyphenyl)pyrazolo[3,4-d]pyrimidine than the activity detected in cytosol (Tanaka et al., 2005; Kassner et al., 2008), reducing the likelihood that Akr1C3 plays a physiologic role in Doxol formation. Other aldo-keto reductases potentially play a role in Dox metabolism. For example, pharmacogenetic studies have suggested Akr1B10 or Akr1B1 may mediate the cardiotoxic effects of Dox (Morikawa et al., 2015; Sonowal et al., 2017). However, as the drugs used in these studies likely targeted other oxidoreductases, it is unclear whether the described effects were mediated by Akr1B10 or Akr1B1. The microsomal enzyme 11 β -hydroxysteroid dehydrogenase 1 (11 β -HSD1) was also recently linked to Doxol formation (Yang et al., 2018). The study showed that Doxol formation in human liver hepatocytes is reduced by treatment with an inhibitor of 11 β -HSD1. Because the inhibitor used was not specific to 11 β -HSD1, inhibition of other oxidoreductases may have been responsible for the effect of the drug on

Fig. 7. Cbr1 levels and Doxorubicin (Doxol)-forming activity in ammonium sulfate-fractionated mouse liver cytosol. (A) Coomassie-stained SDS-PAGE analysis of proteins in ammonium sulfate fractions; 10 μ g of protein loaded per lane. P, pellet; S, supernatant. (B) Immunoblot analysis of Cbr1 in ammonium sulfate fractions; 10 μ g of protein loaded per lane. (C) Relative amount of Doxorubicin produced by each fraction. Reaction conditions were 200 μ M NADPH, 200 μ M Dox, and 12 μ g fraction protein; incubations were for 1 hour at 37°C. Doxorubicin levels were determined by LC-MS/MS. The relative level of Doxorubicin generated is reported in arbitrary units (AU), where the average level in whole cytosol is set to 2200. Error bars represent 1 S.D.; $n = 3$ for all reactions; na, not assayed; sup, supernatant.

Doxol-forming activity in vivo. Furthermore, the current study showed Doxorubicin formation to be predominantly cytosolic rather than microsomal. Moreover, although the inhibitor used was not specific for 11 β -HSD1, it was shown to not inhibit Cbr1. Thus, the reduction of Doxorubicin formation seen following treatment with the inhibitor is further evidence for the existence of enzymes other than Cbr1 that play an important role in Doxorubicin formation.

The current study showed that although Cbr1 contributed significantly to Doxorubicin formation in liver cytosol, currently unidentified enzyme

or enzymes were responsible for the majority of the Doxorubicin formation activity. The immunoclearing approach outlined here provides a method for evaluating the contributions of other potential Doxorubicin reductases such as AKR1C3 or 11 β -HSD1. However, rather than evaluating specific candidate enzymes using an immunoclearing approach, identification of the enzyme(s) responsible for the unaccounted portion of hepatic Doxorubicin formation likely will require exhaustive fractionation of cytosolic proteins to achieve purity, biochemical identification of specific proteins, and subsequent immunoclearing validation. The ammonium sulfate fractionation of mouse liver cytosol described in this study represents a potential first step in this process and demonstrates that fractionation and tracking Doxorubicin-forming activity is a viable method for identifying unknown Doxorubicin reductases.

Acknowledgments

We thank Jeff Morre of the Oregon State University Mass Spectrometry Facility for assistance in developing the Doxorubicin assay, Oregon State University undergraduates Brittany Marshal and Blake Migaki for assistance in constructing expression plasmids and fractionating liver cytosol, and University of Washington undergraduate Claire Chisholm for assistance in assaying protein levels. The primary laboratory was that of G.F.M.
