Abstract

Cytochrome P450 (CYP) 2B6 metabolizes a number of clinically relevant drugs and is one of the most highly polymorphic human P450 enzymes, with the Lys\textsuperscript{262}→Arg substitution being especially common in several genetic variants. Therefore, K262R (2B6*4) was created in the CYP2B6dH background (N-terminal modified and C-terminal His tagged) and expressed in E. coli. The recombinant CYP2B6dH and K262R were purified and studied to investigate the effect of the Lys\textsuperscript{262}→Arg substitution with six of the most potent drug inhibitors of CYP2B6, namely clopidogrel, clotrimazole, itraconazole, raloxifene, sertraline and ticlopidine. K262R showed a > 3-fold increase in the $K_i$ values with clopidogrel, itraconazole, and raloxifene and ~ 6-fold increase in $K_i$ with sertraline, compared with CYP2B6dH. Similarly, K262R showed 2-, 4-, and > 20-fold higher $K_s$ values than CYP2B6dH with clopidogrel, sertraline, and itraconazole, respectively. In contrast, when tested with several known type II inhibitors of CYP2B enzymes, K262R showed a 10-fold lower $IC_{50}$ with 4-(phenyl)pyridine and ~2-fold lower $IC_{50}$ with 4-(4-nitrobenzyl)pyridine or 1-(4-phenyl)benzylimidazole than CYP2B6dH. Subsequent analysis predicted possible in vivo drug-drug interactions between the CYP2B6 substrate efavirenz and drug inhibitors clopidogrel, clotrimazole, itraconazole, sertraline, and ticlopidine. Furthermore, Q172H/K262R (2B6*6), which is the most common genetic variant of CYP2B6 harboring K262R, was created in CYP2B6dH, expressed, purified, and characterized for inhibition. Q172H/K262R showed a > 6-fold increase in $K_i$ with sertraline and clopidogrel compared with CYP2B6dH. The results suggest that individuals, especially homozygotes, with the 2B6*4 or 2B6*6 allele might be less susceptible to drug interactions resulting from P450 inhibition.
Introduction

Although cytochrome P450 2B6 (CYP2B6) is expressed at relatively low levels in the liver (Guengerich, 2005), the enzyme metabolizes important pharmaceuticals including cyclophosphamide, propofol, promazine, methadone, S-mephenytoin, efavirenz, bupropion, imipramine, midazolam, artemisinin, and tamoxifen (Rendic, 2002; Lewis et al., 2004; Zanger, et al., 2007). In addition, CYP2B6 possesses several important genetic variants; among them the most common are K262R (2B6*4), Q172H/K262R (2B6*6) and R487C (2B6*5). Frequencies of the three most common single nucleotide polymorphisms (SNPs) range from 14-49% for Q172H, 17-63% for K262R, and 0-14% for R487C depending on the ethnicity of the population studied (Lang et al., 2004). For example, studies in German males have found a K262R allele frequency of approximately 5% and a SNP frequency of 30% (Lang et al., 2001; Kirchheiner et al., 2003). Single-dose bupropion pharmacokinetic data obtained from 121 individuals showed 1.3-fold increased clearance by individuals with the 2B6*1/*4 genotype (Kirchheiner at al., 2003). A similar study of 169 individuals with efavirenz showed a 17% reduced area under plasma concentration (AUC) in *1/*4 heterozygotes (Rotger et al., 2007). In vitro, K262R has been incorporated into the engineered CYP2B6dH (N-terminal deleted and C-terminal His-tag) by Hollenberg’s group to study structure-function. Compared with CYP2B6dH, K262R shows a > 2-fold increased $k_{\text{cat}}$ for the metabolism of bupropion to hydroxybupropion (Bumpus et al., 2005) and ~ 2-fold increased catalytic efficiency for the metabolism of efavirenz to 8-hydroxyefavirenz (Bumpus et al., 2006). Interestingly, in contrast to CYP2B6dH, K262R is refractory to mechanism-based inactivation by 17α-ethynylestradiol or efavirenz, whereas susceptibility of the variant to inactivation is preserved with bergamottin, $N,N',N''$-
triethylenethiophosphoramide and 8-hydroxyefavirenz (Bumpus et al., 2005; Bumpus et al., 2006).

Drug-drug interactions (DDIs), especially through inhibition of P450-mediated drug metabolism by a co-administered drug, are one of the primary causes of serious adverse events occurring in clinical practice (Dambro and Kallgren, 1988). The presence of polymorphic variants of P450 further complicates the prediction of in vivo DDIs. To address the issues of genotype-dependent DDIs as a result of enzyme inhibition, Tracy and colleagues have used five substrates and a battery of inhibitors with CYP2C9.1 and CYP2C9.3 variants (Kumar et al., 2006). Recently, several clinically relevant drugs, such as clopidogrel, clotrimazole, itraconazole, ticlopidine, sertraline, and raloxifene have been found to be potent inhibitors of CYP2B6 (Walsky et al., 2006). Therefore, in the present study we have studied the effect of the $\text{Lys}^{262}\rightarrow\text{Arg}$ substitution in $\text{K262R (2B6*4)}$ and $\text{Q172H/K262R (2B6*6)}$ genetic variants on the susceptibility of CYP2B6dH to inhibition by important clinical drugs, and predicted the effect on metabolism of the marker CYP2B6 substrate efavirenz in vivo.
Materials and Methods

Materials. 7-Methoxy-4-(trifluoromethyl) coumarin (7-MFC) and 7-hydroxy-4-trifluoromethylcoumarin (7-HFC) were purchased from Invitrogen (Carlsbad, CA). NADPH, drug compounds, and most of the pyridine and imidazole inhibitors were bought from Sigma Chemical Co. (St. Louis, MO). 5-Cyclohexylpentyl-β-D-maltoside (CYMAL-5) was from Anatrace (Maumee OH). Recombinant NADPH cytochrome P450 reductase (CPR) and cytochrome $b_5$ ($b_5$) from rat liver were prepared as described previously (Harlow et al., 1997). Oligonucleotide primers for polymerase chain reaction were obtained from Sigma Genosys (Woodlands, TX). The molecular chaperone plasmid pGro7, which expresses GroES/EL (Nakajima et al., 1994), was obtained from TAKARA BIO (Shiba, Japan). The QuickChange Site Directed Mutagenesis kit was obtained from Stratagene (La Jolla, CA). Ni-NTA affinity resin was purchased from Qiagen (Valencia, CA). All other chemicals were of the highest grade available and were obtained from standard commercial sources.

Mutagenesis, Expression, and Purification. To create K262R, CYP2B6dH was used as the template, and the forward and reverse primers were 5’-CCCAGCGCCCCCAGGGACCTCATCGAC-3’ and 5’-GTCGATGAGGTCCCTGGGGGCGCTGGG-3’, respectively. For Q172H/K262R, K262R was used as the template, and the forward and reverse primers were 5’-ACCTTCCTCTTCCATTACCGCC-3’ and 5’-GGCGGTAATGGAATGGAAGAGGAAGGT-3’, respectively. The resulting constructs were sequenced to verify the desired mutations and absence of unintended mutations (K262R and Q172H/K262R were analyzed at Protein Chemistry Laboratory, University of Texas Medical Branch, Galveston, TX and Retrogen, Inc., San Diego, CA. respectively). CYP2B6dH, K262R,
and Q172H/K262R were co-expressed with GroES/EL in JM109 cells (Stratagene, La Jolla, CA) as described previously (Kumar et al., 2007). The proteins were then extracted and purified by modifying the recently described procedure (Kumar et al., 2007). In brief, the cell extract was loaded onto Ni-NTA resin in the presence of the detergent CYMAL-5. Protein was eluted with 10 mM KPi, pH 7.4, containing 100 mM NaCl, 20% glycerol, 10 mM β-mercaptoethanol, 0.5 mM phenylmethylsulphonyl fluoride, and 40 mM histidine. CYMAL-5 was added to 4.8 mM, and the sample was subsequently loaded onto a CM-Sepharose column. After washing the CM-Sepharose column using 10 mM KPi buffer containing 0.2 mM DTT, 1 mM EDTA, 20% glycerol, and 100 mM NaCl, the protein was eluted using 500 mM NaCl in the above buffer. Eluted protein was dialyzed against 10 mM KPi buffer containing 10% glycerol and 1 mM EDTA with three changes. The P450 content was measured by reduced CO-difference spectra. Protein concentrations were determined using the Bradford protein assay kit (BioRad, Hercules CA).

**Enzyme Inhibition.** 7-MFC O-deethylation was measured in a final reaction volume of 100 µl as described earlier (Oezguen et al., 2008). In brief, the reaction mixture contained 150 µM 7-MFC in the standard reconstitution system (P450: CPR: b5, 1:4:2) at 5 pmol P450 in 50 mM Hepes, pH 7.4, 15 mM MgCl2, and 2% MeOH. The reaction was performed at 37 °C for 5 min using 1 mM NADPH. Nonlinear regression analysis was performed to fit the data using a four-parameter logistic function to derive the $IC_{50}$ values for all the imidazole and pyridine derivatives. The $K_i$ values were determined using the 7-MFC O-deethylation assay in a final reaction volume of 100 µl at 0.5-5.0 µM drug concentrations and 0-50 µM substrate concentrations. For all inhibition studies, 10 pmol P450 was used. The $K_i$ was determined using global fit for competitive inhibition from SpectraLab.
**Spectral Binding.** For binding studies, difference spectra were recorded using 1 µM P450 on a Shimadzu 2401 PC spectrophotometer at 25 °C as described earlier (Muralidhara et al., 2006). In brief, difference in absorbance between the maxima and minima (ΔA) was recorded after the addition of a series of inhibitor concentrations in methanol to the sample cuvette and the same amount of methanol to the reference cuvette. The spectral dissociation constants (Kₘ) were obtained by fitting the data to the equation for “tight binding” \[ 2\Delta A = \left( \frac{\Delta A_{\text{max}}}{[E_0]} \right) \left( (K_D + [I_0] + [E_0]) + ((K_D + [I_0] + [E_0]))^2 - 4[E_0][I_0] \right)^{1/2} \]. All data treatment and fitting of the inhibition and titration curves were performed with our SpectraLab software.

**Analysis of DDIs.** The analysis for DDIs was carried out essentially as described by Tracy and colleagues (Kumar et al., 2006). In brief, the values for plasma concentrations (Cₘₐₓ) of efavirenz as [S], and of drug inhibitors as [I] in a normal population were taken from the literature. The Kᵢ values were from this investigation, and kᵦ and Kₘ values for efavirenz hydroxylation were obtained from a previous study as follows: kᵦ = 4.3 and 7.9 min⁻¹ and Kₘ = 14.3 and 15.9 µM for CYP2B6dH and K262R, respectively (Bumpus et al., 2006). These values for CYP2B6dH or K262R were fit to the equation for competitive inhibition to determine the predicted in vivo activity of the enzyme. The plasma concentrations of efavirenz and drug inhibitors are not known in the population harboring K262R, and therefore, we have used the concentrations as reported in the normal population.
Results

Expression and Thermal Stability of CYP2B6dH and K262R. Heterologous expression of CYP2B6 and genetic variants such as M46V, G99E, K139E, Q172H, K262R, R140Q, and I391N in COS-1 cells yielded lower P450 expression, suggesting decreased P450 stability (Lang et al., 2004). Therefore, we investigated P450 expression of K262R (2B6*4) as described previously (Kumar et al., 2007). The expression of K262R in E. coli under our standard conditions was ~1.5-fold higher than CYP2B6dH. However, the thermal stability ($T_m$) of K262R was 2 °C lower than CYP2B6dH (Supporting fig. 1). The results suggest no major difference in the expression or stability of K262R compared with the wild-type. In this study, we used the dH construct because it shows much higher bacterial expression and solubility, and more facile purification than the full-length wild-type.

Inhibition and Spectral Binding of CYP2B6dH and K262R by Drugs. To investigate the effect of the Lys$^{262}$→Arg substitution on the interaction with the most potent drug inhibitors of CYP2B6 (Walsky et al., 2006), we selected clopidogrel, ticlopidine, clotrimazole, itraconazole, sertraline, and raloxifene (Supporting fig. 2). The results are presented in Figure 1 and Table 1. The $K_i$ values were determined for competitive inhibition of CYP2B6dH and K262R by the six drugs using 7-MFC at concentrations up to 50 µM and 0-20 µM inhibitor concentrations. The $k_{cat}$ and $K_m$ values for 7-MFC oxidation were 3.8 min$^{-1}$ and 5.1 µM for CYP2B6dH and 4.9 min$^{-1}$ and 5.0 µM for K262R, respectively. CYP2B6dH and K262R showed similar $K_i$ values with clotrimazole and ticlopidine (Fig. 1 and Table 1). However, K262R showed a > 3-fold increase in the $K_i$ values with clopidogrel, itraconazole, and raloxifene compared with CYP2B6dH. In addition, K262R showed ~ 6-fold increase in $K_i$ with sertraline compared with CYPB6dH.
Clopidogrel, ticlopidine, itraconazole, and sertraline induced type I difference spectra with a peak at ~388 nm and a trough at ~420 nm (Fig. 2 inset). CYP2B6dH and K262R showed similar $\Delta A_{\text{max}}$ values with clopidogrel, itraconazole, and ticlopidine, whereas the $\Delta A_{\text{max}}$ with sertraline was 3-fold higher in K262R than the wild-type. Compared with CYP2B6dH, K262R showed approximately 2-, 4-, and 20-fold higher $K_s$ values with clopidogrel, sertraline, and itraconazole, respectively (Fig. 2, Table 1). No significant changes were observed in the $K_s$ values of ticlopidine between CYP2B6dH and K262R. However, the experiment could not be performed with raloxifene because it interfered with the measurement of the type I spectral change. At lower concentration of clotrimazole, the majority of CYP2B6dH and K262R P450 was converted into P420 (data not shown).

**Analysis of DDIs in CYP2B6dH and K262R.** Clopidogrel, sertraline, and raloxifene are among the top 100 prescribed drugs in seniors (http://www.marylandspdap.com), who often use multiple drugs simultaneously, suggesting possible drug-drug interactions. Therefore, we analyzed possible DDIs between the established marker drug substrate of CYP2B6, efavirenz, and drug inhibitors of CYP2B6 clopidogrel, ticlopidine, clotrimazole, itraconazole, sertraline, and raloxifene. The analysis was carried out as described in Materials and Methods. The results predicted that while raloxifene would not alter efavirenz metabolism in vivo, clopidogrel or clotrimazole would almost completely abolish the metabolism of efavirenz (remaining activity = 2% and 6%, respectively) by CYP2B6 (Table 2). In addition, the metabolism of efavirenz would be reduced to 15%, 48%, and 57% in the presence of ticlopidine, sertraline, and itraconazole, respectively (Table 2). Although the Lys$^{262}\rightarrow$Arg substitution would not alter the inhibition significantly in most cases, the substitution is predicted to reduce the metabolism of efavirenz to
a lesser extent in the presence of itraconazole (20 vs. 43% inhibition) and sertraline (16 vs. 52% inhibition).

Inhibition of Q172H/K262R by Clopidogrel and Sertraline. Because of the low allele frequency of 2B6*4 and few if any homozygotes, we performed selected inhibition studies with the most common variant harboring K262R, namely Q172H/K262R (2B6*6). This haplotype is found with high frequency (14-62%) as summarized by Zanger and colleagues (Zanger et al., 2007) and 21-60% (Rotger et al., 2007). The latter study reported 10% *6/*6 homozygotes. Clopidogrel and sertraline showed 4- and 6-fold higher $K_i$ values, respectively, with K262R than CYP2B6dH, and therefore, the drugs were tested with Q172H/K262R. The results are presented in Figure 3. Q172H/K262R showed a 6-fold increase in the $K_i$ value with clopidogrel (0.6 µM vs. 0.1 µM) and > 7-fold increase in the $K_i$ value with sertraline (2.2 µM vs. 0.3 µM) compared with CYP2B6dH. The results suggest that the binding affinity of Q172H/K262R with clopidogrel (Figure 3A) and sertraline (Figure 3B) was further reduced compared with K262R. For reference, the $k_{cat}$ and $K_m$ values for 7-MFC oxidation by Q172H/K262R were 1.3 min$^{-1}$ and 49 µM, which are > 2-fold lower and ~10-fold higher, respectively, than the corresponding values for CYP2B6dH or K262R.

Inhibition of CYP2B6dH and K262R by Pyridine and Imidazole Derivatives. We also investigated whether K262R shows altered inhibition by the known CYP2B4dH imidazole (Muralidhara et al., 2006) and CYP2B6 pyridine (Korhonen et al., 2007) type II inhibitors. Four compounds from each imidazole and pyridine groups were selected. Compared with CYP2B6dH, K262R showed a 10-fold lower $IC_{50}$ values with 4-(phenyl)pyridine and 2-fold lower $IC_{50}$ values with 4-(4-nitrobenzyl)pyridine and 1-(4-phenyl)benzylimidazole (Supporting
It is intriguing that with these two model type II inhibitors, the Lys$^{262} \rightarrow $Arg substitution increased affinity unlike with the drugs.

**Molecular Modeling of CYP2B6dH.** A CYP2B6dH homology model was generated using the 4-(4-chlorophenyl) imidazole-bound CYP2B4dH structure (1SUO) as a template by energy minimization using Insight III, and was represented using Pymol graphics (http://pymol.sourceforge.net/) (Fig. 4). Residues 172 and 262 are located in helix E and the G-H loop, respectively. Interestingly, CYP2B4 and CYP2B11 have a His residue at position 172, whereas CYP2B1, CYP2B4, and CYP2B11 enzymes have an Arg residue at 262, suggesting a possible specific role for Gln-172 or Lys-262 in CYP2B6. A molecular model of CYP2B6dH does not predict a role of residue 262 in substrate binding, except that the side chains of Lys and Arg have different orientations. Further in silico analysis suggests that Arg-262 interacts with His-252 (G-helix), Thr-255 (G-helix), and Asp-266 (H-helix) through H-bonds. These H-bonds are not found in Lys-262 suggesting that the additional interactions in K262R contribute to altered drug binding. Recently, we have shown the importance of H-bonds in CYP2B4dH among the non-active site residues Glu-149, Asn-177, Arg-187, and Tyr-190 in substrate specificity, inhibitor selectivity, and protein stability (Oezguen et al., 2008).
Discussion

In this study the recombinant CYP2B6dH, K262R, and Q172H/K262R provided new insights into the interactions of the enzyme with clinically relevant drugs. First, by determining $K_i$ values, we verified and extended previous findings of potent inhibition of CYP2B6 derived from $IC_{50}$ values in liver microsomes or Sf9 cells. Second, the competitive nature of the inhibition shown in our experiments was substantiated by spectral binding assays with four of the drugs, which showed typical Type I spectra. Third, decreased inhibitor potency of clopidogrel, itraconazole, raloxifene, and sertraline for K262R is in contrast to increased potency of three small type II inhibitors. Fourth, the role of the non-active site residue at position 262 in CYP2B6 is consistent with our recent conserved sequence motif analysis of CYP family 2 enzymes. Finally, the lower inhibitor potency of sertraline and clopidogrel for K262R (CYP2B6*4) alone and especially in combination with Q172H (CYP2B6*6) suggests the real possibility of a diminished genotype-dependent drug interaction in vivo.

An earlier report showed that itraconazole yields a type II spectrum with CYP3A4 and can adopt multiple orientations within the CYP3A4 active site, including a catalytically productive mode (type I) and a slowly dissociating inhibitory mode (type II) (Pearson et al., 2006). However, a type I spectrum is observed with CYP2B6dH and K262R, suggesting that the orientation of itraconazole is such that the nitrogen of the ligand is not able to coordinate with the heme iron of the protein. The difference in the mode of binding of itraconazole in CYP3A4 and CYP2B6dH may contribute to the differences in their $K_s$ values (0.019 vs. 0.07 $\mu$M, respectively). A relatively large and flexible active site of CYP3A4 may facilitate the multiple modes of interactions with itraconazole.
Although molecular modeling suggests that Lys-262 in CYP2B6 does not contact ligands directly, this residue is found within a conserved sequence motif (CSM) in CYP family 2 enzymes (\textsuperscript{264}PRDFIDVY\textsuperscript{268}). This motif (CSM 11) is only present in the CYP2B and CYP2C subfamilies, where it has a very high rank order of conservation (Oezguen et al., 2008). In addition, analysis of the individual residues showed that Arg-262 is among the most conserved residues within CSM 11, further suggesting its functional and/or structural importance. Interestingly, Leu-264 is also among the most conserved residues within the motif (Oezguen et al., 2008), and a Leu\textsuperscript{264}→Phe substitution in CYP2B6dH enhances P450 expression and thermal stability (Kumar et al., 2007).

Because ticlopidine and clopidogrel have been shown to be mechanism-based inactivators of CYP2B6-catalyzed efavirenz hydroxylation (Richter et al., 2004; Walsky and Obach, 2007), an in vivo DDI between efavirenz and the inhibitors might be even more pronounced than indicated based on competitive inhibition alone. The AUC ratio of hydroxybupropion to bupropion was reduced by 68% and 90% in the presence of clopidogrel and ticlopidine, respectively, compared with the control, which suggests that both clopidogrel and ticlopidine inhibit the activity of CYP2B6 significantly in vivo as well as in vitro (Turpeinen et al., 2005). Surprisingly, despite the clear inhibition of CYP2B6 by clopidogrel, clotrimazole, itraconazole, sertraline, or ticlopidine, there is no medical documentation on combination therapy utilizing these drugs that may lead to possible side effects. As an exception, there is a report on DDI between efavirenz and itraconazole in a patient with disseminated histoplasmosis and AIDS. The drug combination resulted in persistently elevated urinary histoplasma antigen levels and sub-therapeutic plasma itraconazole concentrations (Koo et al., 2007). Our results and those of Walsky and Obach (2006) suggest that an extensive survey among patients who use CYP2B6-
metabolized drugs in combination with the potent drug inhibitors is highly desirable. Furthermore, individuals, especially homozygotes, with the 2B6*4 or 2B6*6 allele might be less susceptible to drug interactions resulting from P450 inhibition.

The inhibition was performed using a 7-MFC O-deethylaation assay in a standard reconstitution system as described in Materials and Methods.

$^a$ $K_i$ values are shown from each independent determination.

$^b$ Standard errors for fit to the tight ligand binding equation. The data are representative of at least two independent determinations.

The variations between the experiments are ≤ 20%.
Table 2. Potential in vivo drug-drug interactions between efavirenz with drug inhibitors

$^a$C$_{\text{max}}$ of the inhibitors and substrate were obtained from the following literature sources: www.mentalhealth.com/drug/p30-z02.html (sertraline); www.medscape.com/ (raloxifene); www.pharmgkb.org/ (ticlopidine, clopidogrel, and efavirenz); Burgess and Bodey, 1972 (clotrimazole); Goodwin and Drew, 2007 (itraconazole).

$^b$Predicted in vivo activity was determined using the equation for competitive inhibition. The values for [S] and [I] correspond to the estimated in vivo $C_{\text{max}}$ of efavirenz (13.0 μM) and drug inhibitor, respectively. The $K_i$ values were taken from Table 1, whereas $k_{\text{cat}}$ and $K_m$ values were taken from a previous study (Bumpus et al., 2006). Predicted activities for K262R assume that both CYP2B6 alleles are the variant.

$^c$The values in parenthesis indicate the % activity.
