ABSTRACT

Prostaglandin E2 (PGE2), a major product of cyclooxygenase -2 (COX-2), acts as an immunomodulator at the maternal-fetal interface during pregnancy. It exerts biological function through interaction with E-prostanoid (EP) receptors localized to the placenta. The activation of the COX-2/PGE2/EP signal pathway can alter the expression of the ATP binding cassette (ABC) transporters, multidrug resistance protein (MDR) 1 (P-glycoprotein, P-gp; Gene: ABCB1) and the breast cancer resistance protein (BCRP; Gene: ABCG2), which function to extrude drugs and xenobiotics from cells. In the placenta, PGE2-mediated changes in ABC transporter expression could impact fetal drug exposure. Furthermore, understanding the signaling cascades involved could lead to strategies for the control of Pgp and BCRP expression levels. We sought to determine the impact of PGE2 signaling mechanisms on Pgp and BCRP in human placental cells. The treatment of placental cells with PGE2 up-regulated BCRP expression and resulted in decreased cellular accumulation of the fluorescent substrate Hoechst 33342. Inhibiting the EP1 and EP3 receptors with specific antagonists attenuated the increase in BCRP. EP receptor signaling results in activation of transcription factors, which can affect BCRP expression. While PGE2 decreased NFκB activation and increased AP-1, chemical inhibition of these inflammatory transcription factors did not blunt BCRP up-regulation by PGE2. Though PGE2 decreased Pgp mRNA, Pgp protein expression and function were not significantly altered. Overall, these findings suggest a possible role for PGE2 in the up-regulation of placental BCRP expression via EP1 and EP3 receptor signaling cascades.
INTRODUCTION

Inflammation has an important role in the pathophysiology of several common and serious pregnancy disorders that are each associated with adverse outcomes and compromised placental function. The inflammatory responses observed during pregnancy are complex and the result is often dependent on the timing, severity, and type of stimulus. An inflammatory response can be triggered by a wide variety of pathological stimuli, including hypoxia, infection, tissue damage, trauma and cellular stress (Bloise et al., 2013; Guo et al., 2010). It is increasingly clear that different stimuli can induce alternative patterns of inflammatory molecules thereby invoking different regulatory patterns of gene expression (Ho and Piquette-Miller, 2006).

Studies of placental cells and tissue in vitro document their responsiveness to inflammatory stimuli with increased production of cytokines, chemokines, and prostaglandins (PG) (Keelan et al., 2003). PGs are potent mediators of immune responses (Betz and Fox, 1991; Roper and Phipps, 1994; Snijdewint et al., 1993) and inflammation (Gilroy et al., 1999; Trebino et al., 2003). They play a role in many aspects of pregnancy including maternal-fetal tolerance, parturition, and innate immunity. Prostaglandin E2 (PGE₂) is the predominant PG produced by the placenta (Myatt, 1990). As a result, levels at the placental interface are likely higher than in the peripheral circulation. PGE₂ is derived from arachidonic acid (AA) via the activities of cyclooxygenase-2 (COX-2). The effects of PGE₂ are facilitated by specific-membrane bound G-protein coupled EP receptors (EP1-4), which each have distinct signal transduction profiles and often differing cellular actions (Hata and Breyer, 2004).
The activation of COX-2 affects the ATP binding cassette (ABC) transporters, multidrug resistance protein (MDR) 1 (P-glycoprotein, Pgp; Gene: ABCB1), multidrug resistance-associated protein (MRP) 1 (Gene: ABCC1), and breast cancer resistance protein (BCRP; Gene: ABCG2) (Liu et al., 2010; Surowiak et al., 2008), which play important roles in extruding drugs and xenobiotics out of cells. COX-2 up-regulates the expression and activity of Pgp and BCRP in several cell types (Fantappie et al., 2002; Patel et al., 2002). Furthermore, specific COX-2 inhibitors, such as celecoxib and NS398, block the COX-2-mediated increase in Pgp and BCRP, suggesting that PGE2 may be implicated in this response (Arico et al., 2002; Arunasree et al., 2008; Ko et al., 2008; Patel et al., 2002; Roy et al., 2010; Zatelli et al., 2007; Zrieki et al., 2008).

Pgp and BCRP are the most abundant ATP Binding Cassette (ABC) efflux transporters on the apical brush-border membrane of the placenta. These proteins pump compounds back into the maternal circulation and are generally believed to have a protective role (Ceckova-Novotna et al., 2006; Mao, 2008). However, it’s easy to see how problems could arise if they were to prevent drug delivery to the fetus where the medication was intended to have a therapeutic effect. In either instance, changes in Pgp and/or BCRP expression in placenta could effect fetal drug exposure.

The functional expression of Pgp and BCRP can be up or down regulated by exposing placental cells to various inflammatory agents. For example, acute inflammation, such as that mediated by microbial products like LPS, are known to down regulate the expression of several placental transporters, including Pgp (Bloise et al., 2013; Chen et al., 2005; Petrovic et al., 2007; Petrovic et al., 2008; Wang et al., 2005). On the other hand, chronic, sub-lethal exposure to LPS had no effect on overall
placental Pgp activity (Bloise et al., 2013). In other examples of chronic inflammation, such as that observed in subjects with rheumatoid arthritis, Pgp expression is increased (Dumoulin et al., 1997; Llorente et al., 2000). We previously documented up-regulation of placenta Pgp and BCRP expression in the presence of histological chorioamnionitis (Mason et al., 2011). Taken together, the findings suggest there are many interactive and reactive mediators of inflammation that can alter these transporters in the placenta.

To date, studies have primarily focused on the effects of proinflammatory cytokines (Evseenko et al., 2007; Ho and Piquette-Miller, 2006). PGs are released by the actions of proinflammatory cytokines. It has been shown that IL-1β, IL-6, TNFα, and IL-8, directly stimulate PGE2 production by cells obtained from term placenta (Furuta et al., 2000). Surprisingly, there is no information on the effects of PGE2 on ABC efflux transporters in the placenta.

In the present investigation, we tested the hypothesis that PGE2 increases Pgp and BCRP expression and activity in placental cells via distinct EP receptor signaling pathways. Identification of these signaling pathway(s) could provide important information about mechanisms of inflammation on transporter regulation and facilitate the development of strategies to manipulate Pgp and BCRP expression levels via EP receptor inhibition.
MATERIALS AND METHODS

Materials

The PG receptor antagonists 8-chloro-dibenzo[b,f][1,4]oxazepine-10(11H)-
carboxy-(2-acetyl)hydrazide (SC-19220), 6-isoproxy-9-oxoxanthene-2-carboxylic acid
(AH-6809), and N-[[4’-[[3-butyl-1,5-dihydro-5-oxo-1-[2-(trifluoromethyl)phenyl]-4H-1,2,4- triazol-4-yl[methyl][1,1’-biphenyl]-2-yl[sulfonyl]-3-methyl-2-thiophenecarboxamide (L-
161982) were purchased from Caymen Chemical (Ann Arbor, MI). Prostaglandin E₂
(PGE₂), (2E)-N-[(5-bromo-2-methoxyphenyl)sulfonyl]-3-[2-(2-
naphthalenylmethyl)phenyl]-2-propenamide (L-798106), verapamil, fumitremorgin C
(FTC), MK-571, sulprostone, anti-MDR1 monoclonal antibody (clone F4), and Percoll
were purchased from Sigma (St. Louis, MO). 3-[(4-methylphenyl)sulfonyl]-(2E)- propenenitrile (BAY-11-7082) and (E,E,Z,E)-3-Methyl-7-(4-methylphenyl)-9-(2,6,6-
trimethyl-1-cyclohexen-1-yl)-2,4,6,8-nonatetraenoic acid (SR 11302) was from Caymen
Chemical (Ann Arbor, MI) and Tocris Bioscience (R&D Systems, Minneapolis, MN),
respectively. The antibody against BCRP (clone BXP21) was purchased from EMD
Millipore (Billerica, MA). All receptor antagonists were dissolved in DMSO as 10 mM
stock solutions and stored at -20°C; PGE₂ (1 mg/ml) was dissolved in ethanol. The
concentration of DMSO and EtOH after the dilution of compounds to their final
concentrations was 0.1% and 0.5%, respectively. Lipofectamine™ 2000, pNF-κB-Luc
plasmid, and pAP1-Luc plasmid were purchased from Life Technologies (Carlsbad,
CA). The Dual-Luciferase® Reporter Assay System was purchased from Promega
(Madison, WI).

Cell Culture
Jar cells were obtained from American Type Cell Culture (ATCC, Manassas, VA) and cultured in RPMI 1640 supplemented with 10% fetal bovine serum (FBS), 50 units/ml penicillin, and 50 μg/ml streptomycin. Cells were maintained in a humidified atmosphere of 95% air and 5% CO₂ at 37°C.

Human placentas were obtained under a protocol approved by the Institutional Review Board at the University of Kansas Medical Center. Cytotrophoblasts were isolated from healthy placenta delivered at term by cesarean section as previously described (Arroyo et al., 2004) with minor modifications. Briefly, 50 g of villous tissue was digested in Hanks balanced salt solution media (HBSS; Sigma, St. Louis, MO, USA) containing 40 mg of DNAse (Roche Diagnostics, Indianapolis, IN), 100 mg of trypsin (Sigma) and 500 units of dispase (BD Biosciences, Bedford, MA). Digestion was performed at 37°C for 60 min in an orbital shaking incubator at 350 × g. Digest media was strained to remove tissue fragments and then centrifuged for 5min at 500 × g. The cell pellet was resuspended in DMEM media containing 10% fetal calf serum (FCS; Sigma). Cell suspensions were layered on a discontinuous Percoll gradient (5–70%) and spun for 20 min at 1200 × g. Cells between the 40-50% Percoll bands were collected and plated at a density of 6 × 10⁶ cells on a 60 mm² petri dishes. The cells were grown in M199 media, supplemented with 10% FCS, EGF (10 ng/ml), insulin (5 ng/ml), transferrin (10ng/ml), sodium selenite (0.2 nM), and penicillin/streptomycin (100 U/ml) in a 95% air/5% CO₂ humidified atmosphere at 37°C. After 24h in culture, the cells were washed with phosphate-buffered saline, and renewed with media containing 10% FCS and nystatin.
The purity of the isolated cells was determined by immunofluorescent staining using anti-cytokeratin 7 (C7) and anti-vimentin (vim) antibodies. A proportion of ≥90% C7-positive cells (cytotrophoblasts) was considered to be of sufficient purity. Primary trophoblasts from eight different placentas were used for the regulatory experiments, and the data generated were pooled and analyzed collectively.

Assessment of cytotrophoblast cell biochemical differentiation

The β subunit of hCG is produced by terminally differentiated syncytiotrophoblast and was measured as an indicator of cytotrophoblast differentiation in culture after their isolation from term placenta. Culture medium was collected at 24, 48, 72, 96, and 120h of cytotrophoblast cell culture, and stored in aliquots at −80°C. β-hCG was measured by ELISA following the manufacturer’s instructions (DRG International, Springfield, NJ).

PGE2 Measurements

Cells were cultured in their respective phenol-red free, charcoal stripped FBS media for 24h. Cytotrophoblasts were cultured for 4 days at which point media was replaced and collected after 24h. The PGE2 concentration in the media was then determined using a PGE2 ELISA kit (Thermo Fisher Scientific, Rockford, IL) following the manufacturer’s instructions. The sensitivity of the kit was 15.6 pg/mL, and the intra- and inter-assay coefficients of variation were less than 10%. PGE2 concentrations were calculated using a 4 parameter logistic curve fitting program in GraphPad Prism 6.

Treatment

To examine the effect of PGE2 on Pgp and BCRP transporter expression, cells were cultured in their respective phenol-red free medium supplemented with 10% charcoal/dextran-stripped FBS for 24h. Primary trophoblasts were cultured for 4-5 days
to allow for the development of syncytialization. The medium was then replaced with fresh medium containing 5µg/ml [14.8 µM] PGE2 and cell culture continued. For pharmacological interventions of PGE2 receptor specific isoforms, Jar cells were incubated with 10 µM PG receptor antagonists (SC-19220, EP1; AH-6809, EP1 and EP2; L-798106, EP3; L-161982, EP4) for 1h prior to the addition of PGE2 (5 µg/ml). The effects of PGE2 and EP receptor antagonists on mRNA expression were tested at 24h. Multiple time points (6 – 48h) were tested in preliminary studies. At 24h we observed clear and consistent changes in transporter mRNA and protein with PGE2 treatment. In consecutive studies, cells were exposed to an EP3 receptor agonist (Sulprostone, 10 µM) or an EP1 receptor agonist (17-phenyltrinor PGE2) for 24h prior to RNA isolation. Finally, Jar cells were treated with BAY-110782 (10 µM) and SR 11302 (10 µM) for 1h prior to the addition of PGE2. Pgp and BCRP mRNA expression was determined at 24h.

RNA Isolation and Purification

Total cellular RNA was isolated from the cells and purified using the RNeasy Mini kit according to manufacturer’s instructions. Total RNA concentration was determined by ultraviolet (UV) spectroscopy at 260nm and RNA integrity and purity confirmed by 260/280 ratio (>1.8) and separation on a 1% agarose gel followed by visualization with ethidium bromide.

Real Time Quantitative RT-PCR

Primer sequences for both Pgp and BCRP amplifications were previously described (Mason et al., 2011). 18s rRNA was used to normalize mRNA expression levels. Each sample was assayed in duplicate. All primer sets were tested to ensure
efficiency of amplification over a wide range of template concentrations. SYBR Green (Bio-Rad Laboratories, Hercules, CA) was used for amplicon detection. A melt curve was used after amplification to ensure that all samples exhibited a single amplicon. The average $C_t$ value (cycle threshold for target or endogenous reference gene amplification) was estimated using the software associated with the iCycler real-time PCR detection system (Bio-Rad Laboratories). Relative changes in mRNA expression of the target genes were analyzed using the $\Delta \Delta C_t$ method ($2^{-\Delta \Delta C_t}$) (Livak and Schmittgen, 2001). The average $\Delta C_t$ was calculated by subtracting the average $C_t$ value of the endogenous reference gene (18s rRNA) from the average $C_t$ value of the target gene for the treatment and control groups. Fold changes in mRNA expression of target genes from the treatment groups were expressed relative to that of the vehicle control group.

Immunoblot Analysis (Western Blotting)

Whole cell lysates were prepared by washing the cells twice with ice-cold PBS and then adding lysis buffer (50 mmol/L Tris-Cl, pH 7.5, 150 mmol/L NaCl, 1 mmol/L EDTA, 1% Igepal Ca 630, 0.1% SDS, 0.5% SDC, protease inhibitor, phosphatase inhibitor cocktail I, phosphatase inhibitor cocktail II) to each well. The cells were collected in lysis buffer using a cell scraper, and the sample placed on ice and sonicated briefly. The protein content was measured using the Bio-Rad protein assay kit (Bio-Rad Laboratories).

Protein samples were heated in SDS Laemmli loading buffer (1:1 v/v) at 95 °C for 5 min, and total protein (40 µg) was loaded onto a 7.5% SDS–polyacrylamide gel. Electrophoresis was conducted at 100 V. The proteins were transferred overnight at 35
V onto polyvinylidene membrane (PVDF). Nonspecific binding sites were blocked for 1h with 5% nonfat dry milk in PBS-Tween 0.1% (PBS-T). The PVDF membrane was incubated with Pgp antibody (1:500), BCRP antibody (1:1000), and β-actin antibody (1:20,000) at 4°C overnight, washed 3 times with PBS-T, and then incubated with a horseradish peroxidase-linked secondary antibody for 1h at room temperature. The cells were then washed 3 times with PBS-T. Detection of the protein–antibody complexes was accomplished via the use of ECL reagents and chemiluminescent detection.

**Functional Activity**

Efflux transporter-mediated activity was measured by the intracellular accumulation of fluorescent substrates in the presence or absence of specific inhibitors. Drug efflux activity of cells in monolayer culture was measured by inhibition of the cellular uptake of fluorescent Pgp substrates, Calcein acetoxymethyl ester (Calcein-AM) and Flutax-2 (Oregon green-488 paclitaxel), and BCRP substrate, Hoechst 33342. Calcein-AM is a lipophilic, nonfluorescent dye that diffuses into cells where it is cleaved by cytosolic esterase to a green fluorescent dye. Because calcein AM is also a substrate for MRP1, Flutax-2 was used to confirm Pgp activity. Flutax-2 is a commercially available fluorescent derivative of paclitaxel with high diffusion coefficient to cells (Diaz et al., 2003; Jang et al., 2001). Hoechst 33342 is a dye that fluoresces only when bound to DNA. Thus, the amount of transporter activity is inversely proportional to the accumulation of intracellular fluorescence. The selective Pgp and BCRP inhibitors used were verapamil (100 μM), and fumitremorgin C (5 μM), respectively.
For functional studies, Jar cells were plated on 24-well plates at 1 x 10^5 cells/well and incubated for 1 day in phenol red free medium containing 10% charcoal-dextran stripped FBS before study. Primary trophoblasts were seeded at a density of 5 x 10^5 cell/well and cultured for 4 days in growth medium containing 10% charcoal-dextran stripped FBS prior to treatment. Cells were incubated for 24h at 37°C with or without PGE_2 (5 μg/ml). The selective blockers were added for 60min at 37°C prior to treatment with fluorescent substrates. Fluorescent substrates were then added to final concentrations of 0.4 μM (Calcein-AM), 0.5 μM (Flutax-2), and 5 μg/ml (Hoechst 33442). After a 60min incubation period, the cells were washed thrice with cold PBS and lysed in 10 mM Tris-HCl-1% Triton X-100 (pH 7.4). The accumulation of fluorescent substrates was measured on a SpectraMax M5 Microplate reader at 485/535 nm for Calcein-AM and Flutax-2, and 355/460 nm for Hoechst 33442. Relative fluorescent units (RFU) were normalized by protein concentration and expressed as percentage compared to control.

**Luciferase Assay**

pNF-κB-Luc plasmid or pAP-1-Luc plasmid was co-transfected with Renilla luciferase plasmid into Jar cells using Lipofectamine™ 2000 according to the manufacturer’s instructions (Life Technologies). The cells were transfected for 24h, washed, and then treated with PGE_2 (5 μg/ml) for another 24h. Luciferase activity was assayed using the Dual-Luciferase® Reporter Assay System (Promega) according the recommended protocol. The luciferase activity in the cell lysates was measured by luminescence using the TD-20/20 luminometer (Promega) and normalized to total protein. Each treatment group was run in triplicate.
Statistics

All studies were repeated at least three times. Descriptive statistics were performed for each data set. Graphs were plotted, data were transformed, and statistical analysis was carried out using GraphPad Prism 6.0 (GraphPad Software). β-hCG concentrations were log transformed and analyzed using one-way ANOVA followed by Dunnett’s post test. For expression studies, either unpaired Student’s t test or one-way ANOVA followed by the Tukey’s post test was performed as appropriate. Differences in the cellular accumulation of fluorescent substrates were analyzed using a one-way ANOVA followed by Dunnett’s post test. P value < 0.05 was considered to be significant.
RESULTS

Differentiation of cytotrophoblasts in culture

We confirmed prior reports of cytotrophoblast morphological and biochemical differentiation in culture. The morphological changes were accompanied by biochemical differentiation as indicated by increased hCG secretion. Cytotrophoblast β-hCG secretion increased significantly by 72h and peaked at 96h in culture (Supplemental Figure 1).

PGE2 production by Jar cells and primary trophoblasts

To address the possible effect of endogenous PGE2 produced in cell culture we evaluated PGE2 concentrations in culture media from untreated cells. In a 24h culture, Jar cells (5 x 10^5 cells) produced a mean PGE2 concentration of 39.7 ± 2.8 pg/ml (n=4). The basal level of PGE2 produced in 24h by differentiated trophoblasts (6 x 10^6 cells; cultured for 4 days) was 153.4 ± 23.4 pg/ml (n=5).

PGE2 differentially affects BCRP expression in human placental cells

PGE2 increased BCRP mRNA expression nearly 1.9-fold in Jar cells (P < 0.001) and 1.5-fold in human primary trophoblast (P < 0.05) after 24h treatment (Figure 1A). PGE2 decreased PGP mRNA in Jar cells by ~ 50% (P < 0.05) compared to control, but there was no change of expression in human trophoblasts (Figure 1B).

Compared to untreated control, 24h of PGE2 produced a 3.3-fold (P < 0.01) increase in Jar cell BCRP protein and a 1.6-fold (P < 0.05) increase in human primary trophoblasts (Figure 2A). Pgp protein levels were not statistically altered among cells exposed to PGE2 and vehicle (P = 0.29) (Figure 2B).

PGE2 alters BCRP, but not Pgp activity
BCRP functional activity was clearly present in Jar cells and primary tropoblasts, which showed about a 13% and 19% increase, respectively, in Hoechst 33342 accumulation after 60min incubation in the presence of the BCRP selective blocker FTC ($P < 0.05$) (Figure 3A). In agreement with the increased BCRP mRNA and protein levels, PGE$_2$ treatment (5 µg/ml; 24h) decreased the accumulation of Hoechst 33342 over 20% compared to control in Jar cells and around 16% in primary trophoblasts ($P < 0.05$; Figure 3A). Accumulation of the Pgp substrate, calcein AM, was about 30% higher in the presence of verapamil ($P < 0.05$; Figure 3B), but there was no difference when cells were treated first with PGE$_2$. Cells treated with MK 571 also increased cellular accumulation of calcein AM indicating the presence of MRP1 in Jar cells. However, PGE$_2$ had no effect on MRP1 mRNA level as determined by qrt-PCR (Supplementary Figure 2A, B). The treatment of Jar cells with verapamil also increased the cellular accumulation of Flutax-2 by 33% ($P < 0.05$). PGE$_2$ increased Flutax 12%, but this increase did not achieve statistical significance (Figure 3B).

**PGE$_2$ regulates BCRP expression via EP1 and EP3 receptors**

To determine the EP receptors involved in PGE$_2$-mediated up-regulation of BCRP expression, cells were pretreated with an EP receptor antagonist before exposure to PGE$_2$ (5 µg/ml) for 24h. Both the selective EP1 antagonist SC-19220 ($P < 0.05$) and the EP3 antagonist L-798196 ($P < 0.01$) inhibited the induction of BCRP mRNA by PGE$_2$. Treatment of cells with EP4 selective antagonist L-161982 and EP1/2 antagonist AH 6809 slightly reduced BCRP mRNA levels (Figure 4). All EP receptor antagonists tested failed to fully restore Pgp mRNA levels in Jar cells exposed to PGE$_2$ (Figure 5). There was no effect on Pgp or BCRP expression when cells were treated...
with antagonist alone. It should be noted that neither PGE\(_2\) nor the EP receptor antagonists altered EP1 and EP3 receptor levels (data not shown), indicating that the effect of these agents on transporter expression is not attributable to changes in the cellular expression of EP1 and EP3, but rather the signaling pathway involved. Sulprostone (EP3 agonist; 10 \(\mu\)M) increased BCRP mRNA expression in Jar cells 1.7-fold \((P < 0.001)\) while 17-phenyltrinor PGE\(_2\) (EP1 agonist; 10 \(\mu\)M) increased BCRP expression 1.4-fold \((P < 0.05; \text{Figure 6})\).

**PGE\(_2\) stimulates AP-1 and represses NF-\(\kappa\)B activation**

To examine whether NF-\(\kappa\)B and AP-1 mediate PGE\(_2\)-induced BCRP expression in Jar cells, we first transfected the cells with NF-\(\kappa\)B cis-reporter plasmid pNF-\(\kappa\)B-Luc or AP-1 cis-reporter plasmid pAP-1-Luc. Once complete, PGE\(_2\) treatment repressed NF-\(\kappa\)B activation as reflected in a nearly 2.0-fold decrease in luciferase activity at 24h \((P < 0.001)\). AP-1 luciferase activity was increased 2.9-fold in the presence of PGE\(_2\) at 24h \((P < 0.001, \text{Figure 7A})\).

In subsequent experiments, inhibition of NF-\(\kappa\)B and AP-1 with BAY-11-7082 (10 \(\mu\)M) and SR 11302 (10 \(\mu\)M), respectively, had little effect on PGE\(_2\)-induced BCRP up-regulation (Figure 7B). The addition of BAY 11-7082 or SR 11302 alone had no affect on BCRP mRNA levels (data not shown).

**DISCUSSION**

Inflammatory responses during pregnancy can trigger altered expression of placenta transporters, but the factors responsible for these changes remain largely unknown. We find that PGE\(_2\), an immunomodulatory lipid associated with the terminal
phases of cervical softening and uterine contraction, alters the functional expression of BCRP in both immortalized and primary placental cells. PGE$_2$ increased BCRP mRNA and protein expression (Figure 1 and 2, respectively), albeit to a lesser extent in human placental trophoblasts. The results correlate with increased BCRP activity in Jar cells and primary trophoblasts, which was identified by a decrease in the cellular accumulation of its substrate, Hoechst 33342 (Figure 3). These findings are supported by prior studies demonstrating that the administration of a COX-2 inhibitor, celecoxib, which would inhibit PGE$_2$ production, reverses BCRP-related drug resistance via the down-regulation of BCRP mRNA (Kalalinia et al., 2011; Ko et al., 2008).

Activation of COX-2 has also been shown to increase Pgp (Liu et al., 2010; Patel et al., 2002). Thus, we were surprised that PGE$_2$ decreased mRNA levels of Pgp in Jar cells (Figure 1). Though there was a trend toward decreased Pgp protein expression, the differences failed to achieve statistical significance ($P = 0.29$) (Figure 2B). As previously cited, differences at the RNA level do not always closely correlate with ABC protein expression in trophoblast cultures (Evseenko et al., 2006). Furthermore, we found virtually no effect of PGE$_2$ on calcein AM accumulation in Jar cells. Calcein AM is also an MRP1 substrate, which too, is functionally expressed in Jar cells (Evseenko et al., 2007). Although PGE$_2$ had no effect on MRP1 transcripts (Supplemental Figure 2B), MRP1 inhibition with MK-571 increased the cellular accumulation of calcein AM (Supplemental Figure 2A). Paclitaxel may be a better substrate for Pgp, even though it can also be transported by MRP2 (Lagas et al., 2006). MRP2 is poorly expressed in Jar cells (Evseenko et al., 2006), the cellular accumulation of Flutax-2 (i.e. fluorescently labeled paclitaxel) is perhaps more representative of Pgp function. PGE$_2$ modestly
increased Flutax-2 accumulation in Jar cells (Figure 3B). The fact that changes in Pgp gene expression was not followed by similar functional expression indicates there can be changes in placental Pgp gene expression independent of its activity. A disconnect between Pgp gene expression and activity has been previously demonstrated in other placenta models (Bloise et al., 2013; Petropoulos et al., 2010).

There were obvious differences in the extent PGE₂ altered BCRP and Pgp expression in Jar and primary trophoblast cells. This could be attributed to several different factors including those related to immortalization, culture conditions, metabolic status, transporter expression, and inter-individual variability (as in the case of primary cultures). ABC transporter expression varies among the various placental cell lines (Evseenko et al., 2006). The choriocarcinoma Jar cell line has been used to study trophoblast biology and transport in vitro (Atkinson et al., 2003; Coles et al., 2009; Evseenko et al., 2006; Serrano et al., 2007). We chose Jar for the present study because it expresses both Pgp and BCRP at levels detectable for quantitation and shows evidence of functional expression of these transporters.

The most prominent effect of PGE₂ on transporter expression was observed in the Jar cells. In order to more closely evaluate mechanism and identify clear differences, we performed the subsequent studies using these cells. There are several reasons the effect of PGE₂ on transporter expression was more prominent in Jar cells. Differentiation (syncytialization) may explain some or all the observed differences between the two cell models. Jar cells proliferate in culture but do not spontaneously fuse, whereas trophoblast cells form differentiated syncytium by days 4-5. β-hCG is produced by terminally differentiated syncytiotrophoblast and used to assess
cytotrophoblast biochemical differentiation in culture. We found that β-hCG levels dramatically increase around 72h in culture (Supplemental Figure 1). BCRP and Pgp expression appear to change as trophoblasts mature in culture. BCRP levels in primary trophoblasts increased at 120h of incubation relative to those at 24h, while P-gp decreased (Evseenko et al., 2006). Even so, our results were similar for trophoblasts cultured for 1 day (data not shown) or 4-5 days prior to PGE₂ treatment.

Intrinsic differences in the functional expression of the PGE₂ machinery (i.e. COX-2, AA, EP receptors, etc.) and PGE₂ production could also explain observed differences between the cells. For instance, previous reports failed to detect the production of PGE₂ by JEG-3 choriocarcinoma cells. In contrast to primary trophoblasts, it has been suggested that the limited arachidonate releasing capacity of JEG-3 cells might be responsible for the low PGE₂ production (Premyslova et al., 2006). In theory, this could mean that choriocarcinoma cells, such as Jar, are more sensitive to exogenous PGE₂ stimulation compared to the primary trophoblasts. In the present study, we determined that primary trophoblasts seeded at a density of 6 × 10⁶ cells and differentiated for 4 days produced around 153.4 ± 23.4 pg/ml of PGE₂ in 24 h. Jar cells were also capable of producing PGE₂. The mean basal concentration of PGE₂ produced in Jar cells seeded at a density of 5 × 10⁵ cells was 39.7 ± 2.8 pg/ml. We cannot rule out the possibility that endogenous PGE₂ may have some effect on transporter expression.

A primary function of BCRP and Pgp is to transport compounds out of placental cells and prevent access to the fetal circulation. In tissue barriers, BCRP and Pgp often act in concert (de Vries et al., 2007), implying the loss of either transporter alone does not result in an appreciable increase in penetration of dual substrates. For example, in
Pgpa/b knockout mice (where bcrp1 is present) bcrp1 alone is sufficient to limit brain uptake of xenobiotics (Agarwal et al., 2011). The same can be said of mdr1a/b in bcrp1 knockout mice. Thus, the greatest impact on transplacental passage of dual substrates may be seen when both transporters are similarly altered or when one of these transporters is predominately expressed in the cell.

BCRP mRNA levels are highest in placenta compared to other tissues, and it is approximately 10 times greater than Pgp in human term placenta (Ceckova, 2006 #29). Many drugs commonly administered to pregnant women such as glyburide (Zhou et al., 2008), nitrofurantoin (Merino et al., 2005), and cimetidine (Pavek et al., 2005) are BCRP substrates, and its induction may affect how these drugs are distributed and cleared during pregnancy. The importance of BCRP in placenta is further recognized by its presence on the fetal blood vessel endothelial cells (Ceckova et al., 2006; Mason et al., 2011; Yeboah et al., 2006), where it could efflux potentially harmful exogenous and endogenous substrates into the fetal circulation. In this case, up-regulation of BCRP in fetal blood vessel endothelial cells could have an impact on transport toward the fetus. Interestingly, Yeboah et al. (Yeboah et al., 2006) found that neither umbilical cord vein nor arteries express BCRP. They speculated that BCRP expression in the fetal blood vessel endothelial cells may be regulated by the local action of factors derived from the placenta itself. PGE₂ is produced by the placenta and our data links PGE₂ to up-regulation of BCRP, advocating it as a potentially important factor in terms of placental transport.

The heterogeneity of PGE₂ immunoregulatory effects may depend on distinctive signaling mechanisms mediated by different PGE₂ receptors. All 4 membrane receptor
subtypes (EP1-4) have been localized in human placental villous tissue (Grigsby et al., 2006). It is believed their presence in human placenta may indicate autocrine and paracrine roles for PGE₂ in the signaling pathways associated with parturition (Grigsby et al., 2006). We suspect that specific EP receptors are involved in downstream regulation of BCRP and Pgp. We observed that antagonism of the EP1 and EP3 receptors counteracts the increase in BCRP mRNA induced by PGE₂ (Figure 4), and that the EP1 and EP3 agonists alone increased BCRP mRNA expression (Figure 6). Thus, EP1/3 receptors may facilitate PGE₂ signals that modulate placental BCRP expression. Further evaluation may reveal that these receptors are potential pharmacological targets, whereby limiting the responsiveness to PGE₂ during pathologic pregnancy could potentially mitigate BCRP over-expression while maintaining its relevant transport function. This could allow adequate delivery of drugs intended for the fetus without compromising the protective function of BCRP in the placenta.

The greatest impact on BCRP mRNA expression occurred with the EP3 receptor. This receptor is unique among the EP subtypes in that it seems to be the only prostanoid receptor present in the syncytiotrophoblast layer of placenta from women at various stages of labor (Grigsby et al., 2006). Its expression corresponds to the apical membrane localization of BCRP in syncytiotrophoblasts, supporting its potential involvement in BCRP regulation. The EP3 receptor has multiple isoforms generated by alternative splicing. These variants differ in tissue expression, constitutive activity, and regulation of signaling molecules (Adam et al., 1994; Negishi et al., 1995; Schmid et al., 1995). Their expression profile in the human placenta is unknown, but suggests the
potential for isoform-specific regulation of BCRP transcriptional activation. Targeting placenta-specific isoforms of EP3 to regulate BCRP activity could avoid the ever-present possibility of affecting BCRP levels in other tissues.

EP receptor signaling pathways ultimately lead to activation and translocation of transcription factors involved in the regulation of transporter expression. Within the promoter region of BCRP and Pgp are the putative binding sites for both NF-κB and AP-1. These proinflammatory transcription factors could play a role in the regulation of PGE₂ on transporter expression. It has been previously shown that COX-2/PGE₂/EP receptor signaling produces dose dependent changes in the activity of NF-κB (Hu et al., 2008). Others have observed that NF-κB inhibits the transcription of Pgp/mdr1a/b (Ogretmen and Safa, 1999) and induces the transcription of BCRP/Bcrp1 (Pradhan et al., 2010). We found that PGE₂ decreased NF-κB and increased AP-1 activity (Figure 7A) in Jar cells, supporting AP-1 activation as a candidate transcriptional pathway for BCRP up-regulation. It is possible that NF-κB and AP-1 may modulate each other and that activation of AP-1 negatively affects NF-κB activity (Fujioka et al., 2004). While this could explain the effect of PGE₂ on NF-κB activity, inhibition of these transcription factors in PGE₂-treated Jar cells did not interfere with BCRP induction (Figure 7B). This indicates that BCRP mRNA may not be directly regulated by NF-κB or AP-1 when stimulated with PGE₂. Clearly, a broader investigation into the transcription factor profile activated by PGE₂ stimulation would provide insight into those that contribute to the induction of BCRP mRNA.

Both BCRP and Pgp are important elements of barrier function and distinct signaling pathways may regulate their functional expression. This study highlights a
potential role of PGE₂ in regulating BCRP expression in human placenta cells. Given that placental PGE₂ levels rise in response to infection, we postulate that BCRP up-regulation is a placental mechanism to dynamically respond to protect the developing fetus from inflammatory insults, and that PGE₂ is a trigger for this cellular response. We cannot rule out the possibility that other PGs, such as PGF₂α, may also have an effect on Pgp and BCRP expression. It would be interesting then in future investigations to compare the impact of different PGs on transporter activity.

FIGURE LEGENDS

Figure 1. Relative changes in [A] BCRP and [B] PGP mRNA expression was determined by real-time PCR in human placental choriocarcinoma Jar cells \( (n = 3) \) and human primary trophoblast cells \( (n = 8) \) stimulated with PGE\(_2\) (5 \( \mu \)g/ml) for 24h. Samples were normalized to the endogenous reference gene, 18s rRNA, and expressed relative to the vehicle control. The mean fold change was calculated in each sample by the \( 2^{\Delta\Delta C_t} \) method. Treatment with PGE\(_2\) increased BCRP mRNA expression. Data are presented as mean ± S.E.M., *, \( P < 0.05 \); ***, \( P < 0.001 \)

Figure 2. The effect of PGE\(_2\) on [A] BCRP and [B] PGP protein expression was determined by Western blot in human placental choriocarcinoma Jar cells \( (n=3) \) and human primary trophoblast cells \( (n = 8) \). Immunoblots shown are the representative results obtained in typical experiments. Relative protein levels were normalized to \( \beta \)-actin. Band intensity (intensity/mm\(^2\)) was expressed as a fold-change over the average control for 24h PGE\(_2\) treatments. Data are presented as mean ± S.E.M., *, \( P < 0.05 \); **, \( P < 0.01 \).

Figure 3. The functional expression of [A] BCRP in Jar cells and primary trophoblasts and [B] Pgp in Jar cells were evaluated following treatment with PGE\(_2\) (5 \( \mu \)g/ml). Drug efflux activity was determined after 24h PGE\(_2\) exposure, and selective chemical inhibition of the intracellular accumulation of fluorescent BCRP substrate Hoechst 33342 and Pgp substrates calcein-AM and flutax-2. The selective BCRP and Pgp
inhibitors used were fumitremorgin C (FTC, 5 µM) and verapamil (100 µM), respectively. Data are presented as mean ± S.E.M. *, P < 0.05.

**Figure 4.** The effects of PGE₂ receptor (EP) antagonism on BCRP mRNA expression in placental Jar cells. The mean fold change in transporter mRNA expression was calculated in each sample by the 2ΔΔCt method. Ct values of the target gene were normalized to the endogenous reference gene, 18s rRNA, and expressed relative to the vehicle control. Data are presented as mean ± S.E.M., *, P < 0.05; **, P < 0.01; ***, P < 0.001; NS, no significant difference.

**Figure 5.** The effects of PGE₂ receptor (EP) antagonism on PGP mRNA expression in placental Jar cells. The mean fold change in transporter mRNA expression was calculated in each sample by the 2ΔΔCt method. Ct values of the target gene were normalized to the endogenous reference gene, 18s rRNA, and expressed relative to the vehicle control. Data are presented as mean ± S.E.M., *, P < 0.05; **, P < 0.01; ***, P < 0.001; NS, no significant difference.

**Figure 6.** The EP1 receptor agonist, 17-phenyl trinor PGE₂, and EP3 receptor agonist, sulprostone, increases BCRP mRNA expression. The mean fold change in transporter mRNA expression was calculated in each sample by the 2ΔΔCt method. Ct values of the target gene were normalized to the endogenous reference gene, 18s rRNA, and expressed relative to the vehicle control. Results are expressed as the mean ± S.E.M. *, P < 0.05; ***, P < 0.001 compared with vehicle control.
Figure 7. The effect of PGE$_2$ on the activation of transcription factors, NF-kB-and AP-1, and their impact on BCRP transcriptional expression. [A] The effect of PGE$_2$ on NF-kB- and AP-1-dependent transcriptional activity was measured by NF-kB- and AP-1-dependent promoter luciferase reporter gene assay. Cells were co-transfected with pNF-kB-Luc or pAP-1-Luc for 24h, and then exposed to PGE$_2$ (5 μg/ml). The luciferase activity was measured after 24h administration of PGE$_2$. Data for the NF-kB- and AP-1-dependent promoter activity were normalized to luciferase activity from co-transfection of *Renilla* luciferase plasmid. [B] Jar cells were treated with the NF-κB inhibitor, BAY-11-7082 (10 μM), or the AP-1 inhibitor, SR 11302 (10 μM), for 1h prior to stimulation with PGE$_2$ for an additional 24h. BCRP mRNA expression was determined by real time pcr. Neither BAY-11-7082 nor SR 11302 affected the PGE$_2$-mediated up-regulation of BCRP. Values are the means ± S.E.M. *, $P < 0.05$; ***, $P < 0.001$ compared with vehicle control.
